|-----------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |         | <pre> se the script is terminated with `SIGKILL` and the route is unregistered. Value is a string (e.g. "10s") and must parse to a positive tim e duration i.e. "-5s" is not permitted. Must be less than the value of `registration_inter val`.  Default: Half of the value of `registration _interval` +      unrestricted_volume object +      path (required, string): the path to be mounted +      writable (optional, boolean): sets the writable flag. defaults to false + options object lb_algo (optional, string): Load balancing algorithm for routing incoming requests to th e backend: 'round-robin' or 'least-connectio n'. In cases where this option is not specifi ed, the algorithm defined in gorouter spec is applied.  ``` ## Built with go 1.22.6 **Full Changelog**: <a href="https://github.com/cloudfoundry/routing-release/compare/v0.302.0...v0.303.0">https://github.com/cloudfoundry/routing-release/compare/v0.302.0...v0.303.0</a> </pre> |

#### ▼ v0.302.0

```

## 0.302.0
**Release Date**: August 08, 2024
## Changes
- Adds drain_wait + load_balancer_healthy_
threshold properties behaving similarly to go
router's to provide better uptime during BOSH
deployments by waiting for LBs to pull nodes
about to be shut down out of service, and re-
add them before moving on to the next.
- Adds support for TLS backends with TCP r
outes. This enables TCP routes to use the env
oy proxy settings on app containers used by H
TTP routes, providing guaranteed TLS encrypti
on between tcp-router + diego-cell VMs, witho
ut intervention from app teams. Additionally
it allows for the disabling of the unproxied
ports on containers since TCP route traffic c
an now go through envoy.
- Fixed a bug with v0.301.0 that caused pr
oblems with TCP routes when a postgres databa
se was used for the routing-api. Thanks for
[finding this](https://github.com/cloudfoundry/routing-api/issues/57) @schmidtsv!
- Bumped to golang 1.22.5
- Bumped tcp_router's haproxy to 2.8.10
- Testing + docs improvements
## Bosh Job Spec changes:

```

## 6.0.6

**Release Date:** 07/29/2024

### Caution

This release is affected by a known issue for customers who use both Postgres for the TAS for VMs database and TCP Routes. Users who use both Postgres and TCP Routes should not upgrade to this version. This only applies if Postgres is used for the core Cloud Foundry databases, not if apps use Postgres services.

- **[Bug Fix]** Fixes a regression where pushing docker apps with SHA256 digests fails
- **[Bug Fix]** Resolves a rare issue leading to pre-start script failures in the garden-cni + vxlan-policy-agent jobs on diego-cells
- **[Bug Fix]** Scaling factors should be declarative in the autoscaler manifest
- **[Bug Fix]** Accept null body for SLC PUT API
- **[Bug Fix]** Adds 2 minute caching for failed dns lookups in syslog agent to avoid dns load for malformed drain urls.
- **[Feature]** Adds `PrometheusRemoteWrite` exporter and `batch` processor.
- Bump backup-and-restore-sdk to version `1.19.23`
- Bump binary-offline-buildpack to version `1.1.13`
- Bump bpm to version `1.2.23`
- Bump capi to version `1.187.0`
- Bump cf-autoscaling to version `250.3.0`
- Bump cf-cli to version `1.65.0`

- Bump cf-networking to version 3.47.0
- Bump cflinuxfs4 to version 1.107.0
- Bump credhub to version 2.12.83
- Bump dotnet-core-offline-buildpack to version 2.4.31
- Bump go-offline-buildpack to version 1.10.21
- Bump java-native-image-cnb-buildpack to version 0.11.20
- Bump log-cache to version 3.1.1
- Bump loggregator-agent to version 8.1.3
- Bump metric-registrar to version 4.0.1
- Bump nfs-volume to version 7.1.75
- Bump nginx-offline-buildpack to version 1.2.17
- Bump nodejs-offline-buildpack to version 1.8.26
- Bump notifications to version 72.0.0
- Bump notifications-ui to version 48.0.0
- Bump otel-collector to version 0.6.0
- Bump php-offline-buildpack to version 4.6.22
- Bump push-apps-manager-release to version 677.0.49
- Bump push-usage-service-release to version 674.0.114
- Bump pxc to version 1.0.30
- Bump python-offline-buildpack to version 1.8.27
- Bump ruby-offline-buildpack to version 1.10.17
- Bump web-servers-cnb-buildpack to version 0.15.0
- Bump silk to version 3.47.0
- Bump smb-volume to version 3.1.74
- Bump staticfile-offline-buildpack to version 1.6.15
- Bump statsd-injector to version 1.11.41
- Bump system-metrics-scraper to version 4.0.9
- Bump uaa to version 77.14.0

| otel-collector | 0.6.0   | <p>▼ v0.6.0</p> <pre>## What's Changed * Expose wider collector configuration by @acrmp in https://github.com/cloudfoundry/otel-collector-release/pull/31. This allows for configuring processors, pipelines &amp; exporters which provides a lot more flexibility to platform engineers. * Add PrometheusRemoteWrite Exporter by @benjaminguettmann-avtq in https://github.com/cloudfoundry/otel-collector-release/pull/26 * Add batch processor by @acrmp in https://github.com/cloudfoundry/otel-collector-release/pull/32 * Bump go.opentelemetry.io/collector/cmd/builder from 0.103.0 to 0.104.0 in /src/otel-collector-builder by @dependabot in https://github.com/cloudfoundry/otel-collector-release/pull/30 ## New Contributors * @benjaminguettmann-avtq made their first contribution in https://github.com/cloudfoundry/otel-collector-release/pull/26 **Full Changelog**: https://github.com/cloudfoundry/otel-collector-release/compare/v0.5.0...v0.6.0</pre> |

## 6.0.5

**Release Date:** 07/08/2024

### Caution

This release is affected by a known issue for customers who use both Postgres for the TAS for VMs database and TCP Routes. Users who use both Postgres and TCP Routes should not upgrade to this version. This only applies if Postgres is used for the core Cloud Foundry databases, not if apps use Postgres services.

- **[Known Issue]** Running `cf push --docker-image` may fail if specifying the image with SHA256 digests. This will be fixed in a future patch release. Workaround this by using the image tag instead of the digest.
- **[Feature Improvement]** Configure JWKS cache in UAA
- **[Feature Improvement]** Expose proxy metrics for internal MySQL
- **[Bug Fix]** Re-enables parallel applier threads for internal MySQL cluster
- **[Bug Fix]** Route Registrar only sends 5 unregistration messages in a row when a route becomes unhealthy. This prevents Gorouter's logs from filling up with unnecessary, repetitive log messages.
- Bump backup-and-restore-sdk to version [1.19.22](#)
- Bump bpm to version [1.2.22](#)
- Bump capi to version [1.185.0](#)
- Bump cf-autoscaling to version [250.2.5](#)
- Bump cf-cli to version [1.64.0](#)
- Bump cflinuxfs3 to version [0.390.0](#)
- Bump cflinuxfs4 to version [1.103.0](#)
- Bump credhub to version [2.12.80](#)
- Bump diego to version [2.100.0](#)
- Bump dotnet-core-offline-buildpack to version [2.4.29](#)
- Bump java-offline-buildpack to version [4.70.0](#)
- Bump java-native-image-cnb-buildpack to version [0.11.18](#)
- Bump log-cache to version [3.1.0](#)
- Bump mapfs to version [1.2.79](#)
- Bump nats to version [56.21.0](#)

- Bump nfs-volume to version 7.1.74
- Bump nginx-offline-buildpack to version 1.2.15
- Bump otel-collector to version 0.5.0
- Bump php-offline-buildpack to version 4.6.20
- Bump push-apps-manager-release to version 677.0.48
- Bump push-usage-service-release to version 674.0.112
- Bump pxc to version 1.0.29
- Bump python-offline-buildpack to version 1.8.26
- Bump routing to version 0.301.0
- Bump web-servers-cnb-buildpack to version 0.14.1
- Bump smb-volume to version 3.1.73
- Bump syslog to version 12.3.0
- Bump uaa to version 77.12.0

#### ▼ v77.10.0

```

## What's Changed
### New UAA
* Bump to [UAA v77.10.0] (https://github.com/cloudfoundry/uaa/releases/tag/v77.10.0)
### Misc
* [Upgrade Bellsoft JDK to version 17.0.11+12] (https://github.com/cloudfoundry/uaa-release/commit/6b4ec004cfccb61d6bd30e935a39af5fd2822a9)
### Dependency Bumps
* Bump github.com/cloudfoundry/bosh-utils from 0.0.463 to 0.0.464 in /src/acceptance_tests by @dependabot in https://github.com/cloudfoundry/uaa-release/pull/873
* Bump github.com/cloudfoundry/bosh-utils from 0.0.464 to 0.0.465 in /src/acceptance_tests by @dependabot in https://github.com/cloudfoundry/uaa-release/pull/875
* Bump nokogiri from 1.16.4 to 1.16.5 by @dependabot in https://github.com/cloudfoundry/uaa-release/pull/878
* Bump minitest from 5.22.3 to 5.23.0 by @dependabot in https://github.com/cloudfoundry/uaa-release/pull/879

```

## 6.0.4

**Release Date:** 05/29/2024

- **[Feature Improvement]** metric-registrar uses syslog binding cache, reducing load on Cloud Controllers
- **[Bug Fix]** Apps-manager large route list display failure
- **[Bug Fix]** Remove replication-canary
- **[Bug Fix]** App Autoscaler resolves incompatibility with load balancers that reject POST requests without a Content-Length header.
- **[Bug fix]** Automatically restart Route Emitter after multiple failed attempts to greet Gorouter. This fixes a [rare bug](#) that prevented Route Emitter from being able to register routes.
- Bump backup-and-restore-sdk to version [1.19.16](#)
- Bump binary-offline-buildpack to version [1.1.12](#)
- Bump bpm to version [1.2.19](#)
- Bump capi to version [1.182.0](#)
- Bump cf-autoscaling to version [250.2.4](#)
- Bump cflinuxfs4 to version [1.91.0](#)

- Bump credhub to version 2.12.75
- Bump diego to version 2.99.0
- Bump dotnet-core-offline-buildpack to version 2.4.28
- Bump garden-runc to version 1.53.0
- Bump go-offline-buildpack to version 1.10.19
- Bump java-offline-buildpack to version 4.69.0
- Bump java-native-image-cnb-buildpack to version 0.10.4
- Bump mapfs to version 1.2.70
- Bump metric-registrar to version 4.0.0
- Bump mysql-monitoring to version 10.15.0
- Bump nfs-volume to version 7.1.66
- Bump nodejs-offline-buildpack to version 1.8.25
- Bump php-offline-buildpack to version 4.6.19
- Bump push-apps-manager-release to version 677.0.45
- Bump push-usage-service-release to version 674.0.101
- Bump pxc to version 1.0.28
- Bump python-offline-buildpack to version 1.8.25
- Bump r-offline-buildpack to version 1.2.12
- Bump routing to version 0.298.0
- Bump ruby-offline-buildpack to version 1.10.15
- Bump web-servers-cnb-buildpack to version 0.13.2
- Bump smb-volume to version 3.1.68
- Bump uaa to version 77.9.0

| garden-runc | 1.53.0  | <p>▼ v1.53.0</p> <pre> ## Changes - **DEPRECATION NOTICE** The `garden.experimental_use_containerd_mode_for_processes` property and usage of Garden when run in containerd mode for processes is now deprecated and no longer tested. - **DEFAULT CHANGE** - The default mode for garden containers is now containerd. This has been the default in cf-deployment since 2018. - **REMOVAL OF EXPERIMENTAL FUNCTIONALITY NOTICE** The experimental option to run the garden server process in rootless mode has been removed, as it did not work as expected and was an abandoned feature. - Go package dependency bumps ## Bosh Job Spec changes: ```diff diff --git a/jobs/garden-binaries/spec b/jobs/garden-binaries/spec index 0433639a..a8a96bae 100644 --- a/jobs/garden-binaries/spec +++ b/jobs/garden-binaries/spec @@ -15,7 +15,6 @@ packages: - grootfs - xfs-progs - thresholder - - netplugin-shim - dontpanic - tini diff --git a/jobs/garden/spec b/jobs/garden/spec index 027df351..093e53e1 100644 --- a/jobs/garden/spec +++ b/jobs/garden/spec @@ -36,7 +36,6 @@ packages: - grootfs - xfs-progs - thresholder - - netplugin-shim - dontpanic - tini @@ -199,10 +198,6 @@ properties: description: AppArmor profile to use for unprivileged container processes default: garden-default - garden.experimental_rootless_mode: -   description: A boolean stating whether or not to run garden-server as a non-root user -   default: false - # We believe this defaults to false to help concourse: https://github.com/cloudfoundry/garden-runc-release/releases/tag/v1.5.0 </pre> |

Value is a string (e.g. "10s") and must parse to a positive time duration i.e. "-5s" is not permitted. Must be less than the value of `registration_interval`.  Default: Half of the value of `registration_interval` + options object + lb_algo (optional, string): Load balancing algorithm for routing incoming requests to the backend: 'round-robin' or 'least-connection'. In cases where this option is not specified, the algorithm defined in gorouter spec is applied. + example:   - name: my-service uris: @@ -150,6 +154,8 @@ properties: script_path: /path/to/script timeout: 5s route_service_url: https://my-oauth-proxy-route-service.example.com + options: + lb_algo: least-connection - name: my-tls-endpoint tls_port: 12346 server_cert_domain_san: "my-tls-endpoint.internal.com" ``` ## Built with go 1.22.3 **Full Changelog**: <a href="https://github.com/cloudfoundry/routing-release/compare/v0.296.0...v0.297.0">https://github.com/cloudfoundry/routing-release/compare/v0.296.0...v0.297.0</a> ## Resources - [Download release 0.297.0 from bosh.io](<a href="https://bosh.io/releases/github.com/cloudfoundry/routing-release?version=0.297.0">https://bosh.io/releases/github.com/cloudfoundry/routing-release?version=0.297.0</a>).</pre> |

## 6.0.3

**Release Date:** 05/03/2024

This release is susceptible to a [known issue](#) where Gorouter returns an incorrect HTTP status code in response to requests with an "HTTP 100 Continue" interim status header. To

resolve this issue, see the Broadcom Knowledge Base article [Gorouter Returns wrong HTTP response code to client when the request flow uses HTTP 100-continue.](#)

- **[Bug Fix]** Reduce load on Cloud Controller from syslog drain fetching in Syslog Binding Cache and Metric Registrar. In certain instances Cloud Controllers may become unresponsive without this bug fix if they can not handle the load
- **[Bug Fix]** In certain instances Cloud Controllers may become unresponsive because of the load generated by metric-registrar 3.0.0-3.0.3. Rolling back to 2.1.14 will not have any user visible effects and will reduce the load on Cloud Controller substantially.
- Bump loggregator-agent to version [8.1.1](#)
- Bump metric-registrar to version [2.1.14](#)
- Bump mysql-monitoring to version [10.14.0](#)
- Bump nginx-offline-buildpack to version [1.2.14](#)
- Bump ruby-offline-buildpack to version [1.10.14](#)
- Bump staticfile-offline-buildpack to version [1.6.13](#)
- Bump uaa to version [77.8.0](#)

## 6.0.2

**Release Date:** 05/01/2024

This release is susceptible to a [known issue](#) where Gorouter returns an incorrect HTTP status code in response to requests with an "HTTP 100 Continue" interim status header. To resolve this issue, see the Broadcom Knowledge Base article [Gorouter Returns wrong HTTP response code to client when the request flow uses HTTP 100-continue](#).

- **[Bug fix]** Fixed a database performance problem for UAA using MySQL with a large number of users
- Bump backup-and-restore-sdk to version [1.19.12](#)
- Bump binary-offline-buildpack to version [1.1.11](#)
- Bump capi to version [1.180.0](#)
- Bump cf-autoscaling to version [250.2.3](#)
- Bump cf-networking to version [3.46.0](#)
- Bump credhub to version [2.12.72](#)
- Bump diego to version [2.98.0](#)
- Bump dotnet-core-offline-buildpack to version [2.4.27](#)
- Bump garden-runc to version [1.52.0](#)

- Bump go-offline-buildpack to version 1.10.18
- Bump java-offline-buildpack to version 4.68.0
- Bump java-native-image-cnb-buildpack to version 0.10.3
- Bump loggregator-agent to version 8.1.0
- Bump mapfs to version 1.2.68
- Bump nats to version 56.19.0
- Bump nfs-volume to version 7.1.63
- Bump nginx-offline-buildpack to version 1.2.13
- Bump nodejs-offline-buildpack to version 1.8.24
- Bump notifications to version 70.0.0
- Bump php-offline-buildpack to version 4.6.18
- Bump push-usage-service-release to version 674.0.98
- Bump pxc to version 1.0.27
- Bump python-offline-buildpack to version 1.8.23
- Bump r-offline-buildpack to version 1.2.11
- Bump routing to version 0.296.0
- Bump ruby-offline-buildpack to version 1.10.13
- Bump web-servers-cnb-buildpack to version 0.13.0
- Bump silk to version 3.46.0
- Bump smb-volume to version 3.1.66
- Bump staticfile-offline-buildpack to version 1.6.12
- Bump syslog to version 12.2.5
- Bump uaa to version 77.7.0

| loggregator-agent | 8.1.0   | <p>▼ v8.1.0</p> <pre>## What's Changed * Replace usages of `grpc.Dial` with `grpc.NewClient` which does not open connections until necessary * Bump dependencies ### Experimental OTel Collector changes * Added `temporary_emit_otel_traces` property to the loggr-forwarder-agent and loggr-forwarder-agent-windows jobs. Setting this property to `true` activates conversion of appropriately tagged http timers to OpenTelemetry traces (it defaults to `false`). See cloudfoundry/gorouter#407. **Full Changelog**: <a href="https://github.com/cloudfoundry/loggregator-agent-release/compare/v8.0.3...v8.1.0">https://github.com/cloudfoundry/loggregator-agent-release/compare/v8.0.3...v8.1.0</a></pre> <p>▼ v8.0.4</p> <div style="border: 1px solid #ccc; padding: 10px;"> <p>Don't use. It contains the code changes from v8.1.0 but without a semver minor bump to indicate new functionality.</p> </div> |

## 6.0.1

**Release Date:** 04/17/2024

This release is susceptible to a [known issue](#) where Gorouter returns an incorrect HTTP status code in response to requests with an "HTTP 100 Continue" interim status header. To resolve this issue, see the Broadcom Knowledge Base article [Gorouter Returns wrong HTTP response code to client when the request flow uses HTTP 100-continue](#).

- **[Known Issue]** A UAA performance regression causes slow user queries with MySQL when there is a large number of users (fixed in TAS 6.0.2).
- **[Feature]** Add option to enable concurrent read/writes for HTTP/1
- **[Feature Improvement]** Remove requirement for manually enabling log cache syslog ingestion when upgrading
- **[Bug Fix]** Fix pre-start hang in internal MySQL
- Bump backup-and-restore-sdk to version [1.19.10](#)
- Bump bpm to version [1.2.18](#)
- Bump capi to version [1.177.0](#)
- Bump diego to version [2.97.0](#)
- Bump java-native-image-cnb-buildpack to version [0.10.2](#)
- Bump log-cache to version [3.0.12](#)
- Bump loggregator to version [107.0.14](#)
- Bump loggregator-agent to version [8.0.3](#)
- Bump mapfs to version [1.2.66](#)
- Bump metric-registrar to version [3.0.3](#)
- Bump mysql-monitoring to version [10.13.0](#)
- Bump nats to version [56.18.0](#)
- Bump nfs-volume to version [7.1.61](#)
- Bump otel-collector to version [0.4.1](#)
- Bump push-apps-manager-release to version [677.0.42](#)
- Bump push-usage-service-release to version [674.0.96](#)
- Bump pxc to version [1.0.26](#)
- Bump web-servers-cnb-buildpack to version [0.11.1](#)
- Bump smb-volume to version [3.1.64](#)
- Bump smoke-tests to version [4.10.0](#)
- Bump statsd-injector to version [1.11.40](#)

- Bump syslog to version 12.2.4
- Bump system-metrics-scraper to version 4.0.8
- Bump uaa to version 77.5.0

## 6.0.0

**Release Date:** 04/09/2024

This release is susceptible to a [known issue](#) where Gorouter returns an incorrect HTTP status code in response to requests with an "HTTP 100 Continue" interim status header. To resolve this issue, see the Broadcom Knowledge Base article [Gorouter Returns wrong HTTP response code to client when the request flow uses HTTP 100-continue](#).

- **[Known Issue]** A UAA performance regression causes slow user queries with MySQL when there is a large number of users (fixed in TAS 6.0.2).
- **[Breaking Change]** Remove Developer Portal from TAS
- **[Breaking Change]** Change default internal route service port to 7070
- **[Breaking Change]** No longer install cflinuxfs3 by default
- **[Breaking Change]** Replace cpu entitlement counters with cpu\_entitlement percentage gauge
- **[Breaking Change]** Remove (deprecated) Metrics Agent and Metrics Discovery Release
- **[Breaking Change]:** Move and adapt UAA password complexity policies
- **[Breaking Change]:** Remove ability of UAA to serve as a native SAML identity provider (operators can continue to configure UAA to connect to an external SAML identity provider, using the **Authentication and Enterprise SSO** pane of the TAS for VMs tile configuration)
- **[Breaking Change]** Gorouter's deprecated /varz and /healthz endpoints on port 8080 have been removed
- **[Breaking Change]** Absolute CPU Entitlement metrics no longer available. See [details](#).
- **[Breaking Change]** App Autoscaler introduces incompatibility with load balancers that reject POST requests without a Content-Length header.
- **[Feature]** New form option and migration to opt-into allowing Small Footprint TAS to 'full' TAS upgrade.
- **[Feature]** Add support for NTLM authentication in Gorouter
- **[Feature]** CAPI Enable legacy MD5 buildpack paths
- **[Feature]** Adds Diego support for Docker workloads using OCI images
- **[Feature]:** Gorouters can be configured to prefer routing to app instances in the same AZ as the router
- **[Feature]** Operators can now turn off non-TLS load balancer health check endpoints for Gorouter and TCP Router via the "Enable HTTP load balancer health checks" properties in the "Networking" tab
- **[Feature]** dopplers can be scaled to zero
- **[Feature]** Gorouter now supports LB Health Checks over TLS on port 8443
- **[Feature]** Operators can set the property "Maximum number of network policies per app source" in the "App Developer Controls"
- **[Feature]** CF API now includes routability status from App Readiness checks in the /processes/:id/stats endpoint.
- **[Feature]** Expose a custom environment identifier on component logs forwarded via syslog
- **[Feature]** Advanced Configuration: Do not deploy Diego cells
- **[Feature Improvement]** Make database "encrypt key" setting more intentional, to avoid password-manager autofilling of the field
- **[Feature Improvement]** Reintroduce global log rate limit

- **[Feature Improvement]** OTel Collector marks OTLP Sums as monotonic if they originate from a Loggregator counter
- **[Feature Improvement]** Stop logging out of external OIDC provider when logging out of TAS
- **[Feature Improvement]** Operators can select which protocols Routing API will accept via the “Routing API Endpoint Protocol” property in the Networking tab. This property defaults to the backwards compatible option “both” that works with all tile integrations.
- **[Feature Improvement]** Allow to configure w3c tracing headers in router
- **[Feature Improvement]** [Cloud Controller] Add option to configure Instance File Descriptor Limit
- **[Feature Improvement]** Apps using readiness health checks will now see audit.app.process.notready and audit.app.process.ready events reported to `cf events`
- **[Feature Improvement]** Garden now emits an `UnkillableContainers` metric to help identify cells that will be unable to redeploy successfully without operator intervention
- **[Feature Improvement]** Adds opt-in support for NTLM + other challenge-response based authentication using `Authorization: Negotiate` flows by automatically enabling sticky sessions for those requests.
- **[Feature Improvement]** Adds support for `Partitioned` cookies to allow for sticky sessions in embedded contexts.

| staticfile-offline-buildpack | 1.6.11  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| statsd-injector              | 1.11.39 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| syslog                       | 12.2.3  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| system-metrics-scrapers      | 4.0.7   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| uaa                          | 77.4.0  | <p>▼ v77.4.0</p> <pre> ## What's Changed ### New UAA * Bump to [UAA v77.4.0](https://github.com/cloudfoundry/uaa/releases/tag/v77.4.0) ### Dependency Bumps * Bump github.com/cloudfoundry/bosh-utils from 0.0.452 to 0.0.453 in /src/acceptance_tests by @dependabot in https://github.com/cloudfoundry/uaa-release/pull/834 **Full Changelog**: https://github.com/cloudfoundry/uaa-release/compare/v77.3.0...v77.4.0 </pre>                                                                        |
| tanzu-jammy-stack            | 1.0.1   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## TAS for VMs v6.0 Breaking Changes

This page lists breaking changes when upgrading VMware Tanzu Application Service for VMs to v6.0.

### Default stacks no longer include cflinuxfs3

New installations of TAS for VMs v6.0 no longer default to include cflinuxfs3 in the list of stacks. Operators can continue to [Configure Cloud Controller](#) to install cflinuxfs3, if desired.

Upgrading an existing foundation to TAS for VMs v6.0 does not remove cflinuxfs3. Apps running on cflinuxfs3 continue to run as normal, and developers can continue to push applications using the cflinuxfs3 stack. However, if operators [remove cflinuxfs3](#) from an existing foundation, then cflinuxfs3 is no longer installed when deploying TAS for VMs, unless the default stack list is configured to include cflinuxfs3 (see above).

Support for the cflinuxfs3 stack is deprecated and will be removed in a future release of TAS for VMs. If you have not already, migrate all applications off of cflinuxfs3 and remove the stack from your foundations.

## Absolute CPU Entitlement metrics no longer available

The `absolute_entitlement` and `absolute_usage` metrics are no longer emitted for each container. They are replaced by the `cpu_entitlement` metric. If you have any dashboards that reference the `absolute_entitlement` and `absolute_usage` metrics, update the dashboards to use the new metric.

Due to the removal of these metrics, the experimental CPU Entitlement Plug-in no longer functions. If you use this plug-in to view CPU entitlement usage, you can instead view the `cpu_entitlement` metric, for example using the Log Cache cf CLI plug-in.

## Breaking changes if you are starting from TAS 5.0

If you are upgrading from TAS 5.0 to TAS 6.0, review the following breaking changes to ensure a smooth upgrade.

### Change: gorouter enforces stricter content-length headers when transfer-encoding header is set

Versions Introduced

| Product    | TAS           |
|------------|---------------|
|            | <b>4.0.30</b> |
| Version(s) | 6.0.10        |
|            | <b>10.0.0</b> |

#### Why Should I Be Concerned About This Change?

go version 1.23 introduced a security enhancement which now checks if the content-length header is valid when the transfer-encoding header is set. Previously the content-length header was ignored and allowed the response to pass through. This change is desirable as it prevents an attacker from performing request smuggling or response splitting.

#### How Can I Tell If I'm Impacted?

After upgrading gorouter will return http status 502 when a response has an invalid content-length header and the transfer-encoding header is set.

#### What Should I Do About It?

This KB [Gorouter returns 502 error when apps returns http status 200 with invalid content length](#) has more information about symptoms and why it is important to fix apps which are sending invalid content-length headers.

## App Autoscaler API requires JRE 17

Versions Introduced

| Product    | TAS            |
|------------|----------------|
|            | <b>2.11.37</b> |
| Version(s) | <b>2.13.19</b> |
|            | <b>3.0.9</b>   |
|            | <b>4.0.1</b>   |

### Why Should I Be Concerned About This Change?

The App Autoscaler API may error during deployment due to it now requiring JRE 17.

### How Can I Tell If I'm Impacted?

You are impacted if you have customized the java offline buildpack to use a JRE other than OpenJDK and the default JRE version in the buildpack or defined by an environment variable group is not JRE 17.

You are likely impacted if the following line appears in the logs for the autoscale-api application:

```
ERR java.lang.UnsupportedClassVersionError:  
org/springframework/boot/loader/JarLauncher has been compiled by a more  
recent version of the Java Runtime (class file version 61.0), this version of the Java  
Runtime only recognizes class file versions up to 55.0
```

### What Should I Do About It?

Ensure that JRE 17 is available in your java offline buildpack.

If the java runtime you are using is the Oracle JRE, then upgrade to a version of TAS that ships with cf-autoscaling version 249.2.6. As of that version of cf-autoscaling, the autoscale-api application configures [JBP\\_CONFIG\\_ORACLE\\_JRE](#) to self-select Oracle JRE 17.

Alternatively, customers can temporarily override their buildpack defaults in order to run the `deploy-autoscaler` errand:

1. Set an environment variable group that changes the default version of Java to 17 across all applications in a foundation, e.g.

```
$ cf set-staging-environment-variable-group '{"JBP_DEFAULT_OPEN_JDK_JRE":{"jre:  
{version: 17.+ }}}'
```

2. Generate the correct parameters for your java runtime by viewing the options available in the [java buildpack](#). Also be careful to merge your new parameters with any parameters already set in the environment variable group.

3. Trigger the deploy-autoscaler errand and see it succeed.
4. Remove the parameters that you added to the environment variable group and re-set the remaining parameters to undo your changes.

## Background

The App Autoscaler API was bumped to JRE 17. Affected versions set the required JRE version with an OpenJDK JRE specific environment variable.

## Spring Boot 3 & Java Buildpack AutoReconfiguration

### Versions Introduced

| Product    | TAS         |
|------------|-------------|
| Version(s) | <b>2.11</b> |
|            | <b>2.13</b> |
|            | <b>3.0</b>  |
|            | <b>4.0</b>  |
|            | <b>5.0</b>  |

### Why Should I Be Concerned About This Change?

The Spring AutoReconfiguration library supplied by the buildpack is deprecated, as well as the Spring Cloud Connectors project. It is recommended to use the [java-cfenv](#) library instead for accessing bound services in Spring Boot apps. To make it easier to migrate to this library, the Java Buildpack will now install the Java CfEnv library for Spring Boot 3 apps only, and the Spring AutoReconfiguration library will no longer be installed for these apps.

### How Can I Tell If I'm Impacted?

Apps may be affected if they have already been migrated to Spring Boot 3 and are relying on Spring Autoreconfiguration, i.e.

1. You have not set the variable `JBP_CONFIG_SPRING_AUTO_RECONFIGURATION '{enabled: false}'`
2. The app is bound to a service of one of these types:
  - Cassandra
  - Relational Database
  - RabbitMQ
  - Mongo DB
  - Redis
  - SMTP
3. The startup logs for the app will show a log entry such as '`dataSource`' bean of type with '`javax.sql.DataSource`' reconfigured with '`mysql`' bean

Apps using Spring Boot 2.x will continue to receive the Spring AutoReconfiguration library and should not be affected by this change.

### What Should I Do About It?

In most cases, the Java CfEnv library should replace the functionality of the Spring Autoreconfiguration library for Spring Boot 3 apps. The Java CfEnv library examines bound services of the above types (except SMTP) and sets well-known Spring Boot properties so that Spring Boot's Autoconfiguration can kick-in.

### Background

The Spring AutoReconfiguration library uses the Spring Cloud Connectors project which has been deprecated since 2019. Java CfEnv is the recommended library for accessing bound services.

## UAA's SAML IdP functionality removed

### Why Should I Be Concerned About This Change?

UAA's ability to act as a SAML identity provider has been removed in preparation for replacing its dependency on Spring SAML Extension with Spring Security SAML 2 support. You can no longer use UAA as your SAML IdP.

Note that UAA's ability to integrate with an upstream SAML identity provider as a SAML service provider is unaffected by this change.

### How Can I Tell If I'm Impacted?

If you use UAA as a SAML IdP, you are impacted. If you are unsure, get the list of registered SAML service providers from UAA's "/saml/service-providers" endpoint. (See

<https://docs.cloudfoundry.org/api/uaa/version/76.31.0/#list>.) If you get a non-empty list in response, then you are using UAA as a SAML IdP.

Note that "/saml/service-providers" endpoint has been also removed from the latest UAA version as part of the SAML IdP functionality removal.

### What Should I Do About It?

UAA now supports acting as an identity provider over OIDC. If the system that acts as a SAML service provider can also integrate with OIDC identity providers, you should switch it to use that protocol instead.

### Background

Spring SAML Extension has reached the end of support. UAA is replacing it with Spring Security SAML 2 support to keep the SAML feature compatible with latest Spring versions. Since Spring Security does not provide Identity Provider support, UAA is dropping its SAML IdP functionality.

## Local UAA password policy configuration changed

### Why Should I Be Concerned About This Change?

If you have customized the password policy settings for local UAA users, these settings will be restored to the default policy unless you take action.

#### How Can I Tell If I'm Impacted?

If you currently have configured the local UAA user password policy by setting the fields under the “Internal user store” option in the Authentication and Enterprise SSO pane, then your existing settings will be affected.

#### What Should I Do About It?

You can instead configure the password policies for local UAA users in a new section on the UAA pane of the TAS tile. This configuration section is available in TAS 4.0 and 5.0 and will be preserved in the upgrade to 6.0.

#### Background

In previous TAS versions, the local UAA password policies could be configured only if you selected the Internal user store option in the Authentication and Enterprise SSO pane. The local UAA password policy configuration option is now moved to the UAA pane, where you can customize the settings regardless of the Authentication and Enterprise SSO option you chose.

## Gorouter uses port 7070 by default for internal route services instead of a random available port

#### Why Should I Be Concerned About This Change?

This change is only relevant to foundations with third-party services listening on port 7070.

#### How Can I Tell If I'm Impacted?

SSH into a router VM and use `lsof -Pi` to determine if port 7070 is being used. Be sure to check any routers deployed by IST as well.

#### What Should I Do About It?

If your foundation is impacted, use Tanzu Operations Manager to configure use of a different port.

For TAS, go to the Networking tab and scroll down to the Route Services section. If route services are enabled, you will see a text box labeled “The port used for internal route services requests.” Set the value to a known available port, or set the value to 0 to allow the operating system to choose an available port at deploy time.

For IST, go to the Networking tab and scroll down to the text box labeled “The port used for internal route services requests.” Follow the same instructions as you did for TAS.

## Breaking changes if you are starting from TAS 4.0

### MySQL 5.7 external system database support removed

## Why Should I Be Concerned About This Change?

Your TAS deployment will fail or become insecure if you are using MySQL 5.7 as TAS's external system database, as MySQL 5.7 will soon reach End-Of-Life.

## How Can I Tell If I'm Impacted?

You are impacted if you have configured a MySQL 5.7 database instance as the external system database for your TAS deployment. You can check your current system database settings by selecting "Databases" pane in the TAS for VMs tile. If under "System databases location" section, the "External database server" option is selected and the configured database server is based on MySQL 5.7, you are impacted.

## What Should I Do About It?

Upgrade your external system database to a supported MySQL version (such as MySQL 8.0).

### Background

This change was triggered by the fact that as MySQL 5.7 reaches its official End-Of-Life date (31 Oct 2023), many TAS components as well the database client libraries that they depend on will follow suit to remove support and testing for MySQL 5.7.

## NATS intentionally fails deployment in post-start in v1

### Why Should I Be Concerned About This Change?

Operators can ensure successful deployment of NATS servers, which propagate routes from services and apps to Gorouter, by confirming that their nats-release instances have successfully migrated to NATS v2.

### How Can I Tell If I'm Impacted?

If your TAS environment is already on v2.11.26 or greater, make sure that your NATS instances have successfully migrated by checking that NATS 2.0 is running (see KB article in link).

### What Should I Do About It?

If your deployment fails, check nats instance logs. Migration details, including any possible error messages, can be found under `/var/vcap/sys/log/nats-tls/nats-tls-wrapper.stdout.log`

### Background

In TAS v2.11.26, nats-release upgraded its underlying software package from NATS 1.0 (package name `gnatsd`) to NATS 2.0 (package name `nats-server`). The nats-release contains NATS 1.0, which will start as a fallback in case the migration to NATS 2.0 fails. In preparation for the future removal of NATS 1.0, nats-release will fail in post-start if it detects that NATS 1.0 is running instead of NATS 2.0.

### Links

- [How to confirm your nats servers are running NATS v2](#)

## App Autoscaler API no longer accepts trailing slashes

### Why Should I Be Concerned About This Change?

Existing clients of the App Autoscaler API may break if they make requests to resources including trailing slashes.

### How Can I Tell If I'm Impacted?

If you have written code that makes requests to the App Autoscaler API with trailing slashes or have documentation that describes making requests with trailing slashes you are impacted.

Requests that specify trailing slashes will now receive a 404 response.

This does not affect users who are using the autoscaler cf CLI plugin.

### What Should I Do About It?

Modify your client or documentation to no longer make requests with trailing slashes.

### Background

This is a Spring Framework default change to improve security posture:

<https://github.com/spring-projects/spring-framework/issues/28552>

## Logging timestamp format changed for some TASW jobs

### Why Should I Be Concerned About This Change?

Existing automation that parses logs from TASW components may break if they are still expecting timestamps formatted as epoch time. Specifically, logs from `groot` and `garden_windows` have been converted to RFC 3339 timestamps.

### How Can I Tell If I'm Impacted?

You are impacted if you have log parsing for TASW's `groot` and `garden_windows` jobs that rely on timestamps being in epoch format.

### What Should I Do About It?

If it was necessary to adjust log parsing for TAS/TASW 4.0 to account for the change in timestamp format, update log parsing in the same manner, but for the TASW `groot` and `garden_windows` jobs.

### Background

Non-standardized and non-human readable timestamps in logs make debugging TAS more difficult. Starting in TAS/TASW 4.0, timestamps have been logged using RFC 3339 format in all cases but `groot` and `garden_windows`.

## Logging timestamp format property removed

### Why Should I Be Concerned About This Change?

Existing automation that configures a log timestamp format will break if product config is not updated.

### How Can I Tell If I'm Impacted?

You are impacted if you set the `logging_timestamp_format` product config property.

### What Should I Do About It?

This property has had no effect since TAS 4.0. Update your configuration to no longer specify the property.

#### Background

Non-standardized and non-human readable timestamps in logs make debugging TAS more difficult.

## Syslog Aggregate Drains property changes

### Why Should I Be Concerned About This Change?

Existing automation that configures aggregate syslog drains will break if product config is not updated.

### How Can I Tell If I'm Impacted?

You are impacted if you have configured aggregate syslog drains with the `syslog_agent_aggregate_drains` property.

### What Should I Do About It?

References to the old property should be updated to refer to the new `mtls_syslog_agent_aggregate_drains` property.

This property is used to define aggregate syslog drains with keys and certificates for Mutual TLS, as well as to define aggregate drains that are not using Mutual TLS.

Comma-separated strings are no longer accepted, instead pass an array of aggregate drains:

```
.properties.mtls_syslog_agent_aggregate_drains:
value:
- url: syslog-tls://HOSTNAME:PORT
- url: syslog-tls://ANOTHER-HOSTNAME:PORT
```

Additionally, consider if your syslog aggregate drains should be updated to use Mutual TLS.

#### Background

From TAS 5.0 operators can configure aggregate drains that support Mutual TLS for improved security. This necessitated changing the structure of the syslog aggregate drains property to allow these new fields to be specified.

## Metrics Agent deprecated and defaults to off

### Why Should I Be Concerned About This Change?

The behavior of any custom integration using Prometheus to scrape the Metrics Agent will change. The Metrics Agent is protected by mutual TLS, and would require using a certificate issued by TAS to access. We do not know of any products or integrations which use this agent.

### How Can I Tell If I'm Impacted?

You would have built a custom integration which scrapes all VMs via Prometheus on port 14726.

### What Should I Do About It?

If you are using the Metrics Agent, it is possible in TAS 5.0 to re-enable it by unchecking the checkbox in the System Logging configuration page. We would encourage you instead to switch to using the Prometheus Exporter in the OpenTelemetry Collector. If you

are unable to migrate to the Prometheus Exporter please let VMware know as the Metrics Agent is slated for removal in TAS 6.0.

### Background

The Metrics Agent was designed as a way for Healthwatch and other components to retrieve metrics without using the Loggregator Firehose. No components ended up adopting it, and with the introduction of the OpenTelemetry Collector we have much more flexible options for egress metrics so are slating this for removal instead of driving adoption towards it.

## Breaking changes if you are starting from TAS for VMs v3.0

If you are upgrading from TAS v3.0 to TAS v6.0, review the following breaking changes to ensure a smooth upgrade.

### Components logs always use Human-Readable RFC 3339 Timestamp Format

#### Why Should I Be Concerned About This Change?

From TAS 4.0.0 components logs are always output with RFC 3339 timestamps.

#### How Can I Tell If I'm Impacted?

Check the “System Logging” pane in the TAS configuration. If “Timestamp format for component logs” is set to “Maintain previous format” then you are impacted.

The corresponding product configuration is where `.properties.logging_timestamp_format` is set to `deprecated`.

#### What Should I Do About It?

If you have systems that rely on the old timestamp format for component logs when parsing log lines then these will need to be updated to handle the RFC 3339 timestamp format.

## Background

Non-standardized and non-human readable timestamps in logs make debugging TAS more difficult.

## Option to Enable (Beta) Log Rate Limit Removed

### Why Should I Be Concerned About This Change?

The option to set a global app log rate limit in TAS/IST/TASW was removed.

If you were using this feature to limit your overall app log throughput, then you may see an increase in log load after upgrading.

### How Can I Tell If I'm Impacted?

If you have enabled the App log rate limit option in the TAS/IST/TASW “App Containers” tab then you are impacted.

### What Should I Do About It?

You should look to replace use of this feature with org, space, and app, byte-based log rate limits. For details, see [App Log Rate Limits](#).

If you are impacted and concerned about log load in your system during, and after, upgrading, consider either:

- Scaling up your logging system before upgrading to TAS v4.0 to compensate for the increased log load.
- Upgrading to TAS v3.0 first to set app-level log rate limits while retaining the global app log rate limit.

## Background

Since the introduction of org, space, and app log rate limits in TAS v3.0, this feature was moved from beta to deprecated.

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#breaking-changes>
- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/app-log-rate-limits.html>

## Recent logs endpoint removed from traffic controller

### Why Should I Be Concerned About This Change?

This will cause versions of the cf CLI before v6.52.0 to no longer be able to retrieve logs when called with `cf logs --recent`.

### How Can I Tell If I'm Impacted?

If you have users or automation that are using cf CLI versions that are older than v6.52.0, they are impacted.

### What Should I Do About It?

Upgrade clients to a newer version of the cf CLI.

### Background

The cf CLI has been using Log Cache as the source for `cf logs --recent` since v6.52.0. This change is removing a deprecated path for log retrieval. cf CLI v6 is not compatible with TAS 2.13 or higher, this is a special notice of removal.

### Links

## Add validation for CAs trusted by Gorouter

### Why Should I Be Concerned About This Change?

If you have invalid CA certificates listed in your Ops Manager and TAS configurations, you will need to update these in order to deploy TAS 4.0.

### How Can I Tell If I'm Impacted?

Any entries that are not valid for CA certificates cause an error in Ops Manager. You must remove or replace invalid entries.

Check any CA certs specified in your Director or TAS tiles against `openssl x509 -text -in <cert-file>`. If any errors are returned, you should fix or regenerate the certificate.

### What Should I Do About It?

Replace the invalid CA certificates with up-to-date and valid certificates. Alternatively, if there is no replacement, simply remove the invalid CA certificate.

### Background

Previously, Gorouter and Opsmanager would ignore the invalid certificates. This change has been made to help make operators aware of any copy/paste problems when applying CA certificates.

### Links

## Max request header size now defaults to 48 kb

### Why Should I Be Concerned About This Change?

If end-users are sending requests with large request headers to your environment, they may now experience 431 status code errors.

### How Can I Tell If I'm Impacted?

You will see 431 status code in your gorouter access logs, with the `X-Cf-RouterError: max-request-size-exceeded` response header set.

### What Should I Do About It?

If you want to accommodate large request headers, you can increase the default size in the [Networking](#) tab of Ops Manager under the field `Maximum request header size`. We do not recommend this accommodation as a long-term option.

### Background

**NOTE:** This limit is specifically for the Method, Request URI, and protocol line of an HTTP request, as well as any HTTP Headers in the request.

Max request header size now defaults to 48 kb. Upgrading to 4.0 sets the Max request header size in kb to 48, unless the existing configuration was already lower. Lowering this value establishes a better security posture; large request headers could consume router resources or leak memory.

## Ruby Buildpack 1.9.0 defaults to Ruby 3.1

### Why Should I Be Concerned About This Change?

If your apps haven't been upgraded to be compatible with Ruby 3.1, you may experience errors.

### How Can I Tell If I'm Impacted?

You will see app errors, logged in

```
cf logs [APP NAME] --recent
```

### What Should I Do About It?

Update your apps to be compatible with Ruby 3.1. If you need a temporary workaround while upgrading apps, you can upload both the Ruby Buildpack 1.9.0 as well as a previous buildpack to your environment until apps have been upgraded and the previous buildpack can be removed.

### Background

### Links

- <https://broadcomcms-software.wolkenservicedesk.com/external/article?articleNumber=298293>

## Viewing Custom iptables Rules Requires /sbin/iptables Binaries

## Why Should I Be Concerned About This Change?

If you create custom iptables rules on your Diego cells, they may not be visible when running `iptables -L` because we have upgraded the default version of iptables. However these custom rules do still apply.

## How Can I Tell If I'm Impacted?

You can see any custom rules you have by running `iptables-legacy`, to evoke iptables 1.6.x.

## What Should I Do About It?

Update your custom iptables logic to use the `/sbin/iptables*` binaries, which run iptables 1.8.x (backed by nftables).

If you need to interact with your custom rules before upgrading, you can use the command `iptables-legacy` as a short-term workaround.

## Background

On the Jammy Jellyfish stemcell, the `iptables` command uses the nftables framework (1.8.x) instead of the `iptables` firewall (1.6.x). We made garden default to using the system `iptables` binary. However, we make both versions available to make custom `iptables` rules accessible in the short-term.

## Links

- <https://broadcomcms-software.wolkenservicedesk.com/external/article?articleNumber=298293>

## Breaking changes if you are starting from TAS for VMs v2.13

If you are upgrading from TAS v4.0 to TAS v6.0, review the following breaking changes to ensure a smooth upgrade.

### App logs that exceed rate limit are dropped immediately

#### Versions Introduced

| Product    | TAS     | Isolation Segment | TAS Windows |
|------------|---------|-------------------|-------------|
| Version(s) | 2.11.26 | 2.11.20           | 2.11.20     |
|            | 2.12.18 | 2.12.13           | 2.12.12     |
|            | 3.0.0   | 3.0.0             | 3.0.0       |

#### Why Should I Be Concerned About This Change?

The behavior of line-based application log rate limiting has changed. Previously application logs would be buffered to some extent and then released at the configured rate. Now application logs that exceed the rate limit are dropped immediately.

## How Can I Tell If I'm Impacted?

You are impacted if you have configured the deprecated line-based application log rate limiting and have applications that emit logs in excess of the configured limit.

## What Should I Do About It?

This is expected behavior and helps ensure that logs that are output are timely. VMware recommends use of quota-based log rate limits for fine-grained control over application log rates.

## Background

This behavior was modified as part of changes to Diego to support granular log rate limits on orgs, spaces and individual apps in TAS 3.0.

## Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#2-13-10>

## Syslog Drains reject SHA-1 certificates

### Versions Introduced

| Product    | TAS            | Isolation Segment | TAS Windows    |
|------------|----------------|-------------------|----------------|
| Version(s) | <b>2.11.19</b> | <b>2.11.13</b>    | <b>2.11.13</b> |
|            | <b>2.12.12</b> | <b>2.12.7</b>     | <b>2.12.7</b>  |
|            | <b>2.13.5</b>  | <b>2.13.2</b>     | <b>2.13.2</b>  |
|            | <b>3.0.0</b>   | <b>3.0.0</b>      | <b>3.0.0</b>   |
|            | <b>4.0.0</b>   | <b>4.0.0</b>      | <b>4.0.0</b>   |

### Why Should I Be Concerned About This Change?

System Logging will be impacted if older SHA-1 hash function certificates are used.

## How Can I Tell If I'm Impacted?

Review your configured application syslog drains. If you have a certificate for a syslog drain configured with a SHA-1 hash, you are impacted.

## What Should I Do About It?

Regenerate impacted certificates so that they don't use the SHA-1 hash function.

## Background

Logging components provided by loggregator-agent-release have been upgraded to Go 1.18. From Go 1.18 the treatment of certificates is stricter and certificates signed with the SHA-1 hash function will be rejected. Go stopped accepting certificates signed with the SHA-1 hash function because of security concerns.

## Links

- <https://go.dev/doc/go1.18#sha1>

## Application log rate limit default

### Versions Introduced

| Product    | TAS   |
|------------|-------|
| Version(s) | 3.0.0 |
|            | 4.0.0 |

### Why Should I Be Concerned About This Change?

Applications pushed to TAS 3.0+ will inherit a default operator-configurable log rate limit if one is not specified.

### How Can I Tell If I'm Impacted?

You are impacted if you are upgrading to TAS 3.0+ and are pushing applications to the platform. Applications that already exist on the platform prior to upgrade will default to not being log rate limited.

### What Should I Do About It?

Determine if the default log rate for new applications (16 K/s) is appropriate for your needs. If you have applications with verbose logs exceeding the default limit and do not wish their logs to be dropped for exceeding the limit then consider:

- pushing your applications with a specified app log rate limit
- modifying the platform default log rate limit

The default log rate limit for new applications is configurable in the “App Developer Controls” tab in the TAS product configuration. The corresponding property is

`.properties.cloud_controller_default_log_rate_limit_app.`

### Background

The ability to set the log rate limit in a granular way is intended to allow operators to protect both the logging system within TAS and external integrations that receive logs. Setting a platform default limit for new applications makes it more likely that applications will have a log rate limit set allowing quotas to be imposed.

## Autoscaler service bindings duplicate index

### Versions Introduced

| Product    | TAS                                               |
|------------|---------------------------------------------------|
| Version(s) | <b>2.11.20</b><br><b>2.12.13</b><br><b>2.13.5</b> |

### Why Should I Be Concerned About This Change?

Upgrading to a version of TAS that introduces a new database index for App Autoscaler on the service bindings table may error if you have previously manually created the same index.

### How Can I Tell If I'm Impacted?

You are impacted if you have previously manually added a database index following the instructions in the knowledge base article Autoscale application fails with MySQL Deadlock errors and are upgrading to one of the following TAS versions:

- 2.13.5
- 2.13.6

### What Should I Do About It?

Upgrade to a newer patch release of TAS that does not have this limitation.

### Background

An error was made in the implementation of the database migration that meant that an attempt was made to add the database index despite it already existing in the database.

### Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#2-13-5>
- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#2-13-7>
- <https://broadcomcms-software.wolkenservicedesk.com/external/article?articleNumber=298085>

## BOSH System Metrics Forwarder Removed

### Versions Introduced

| Product    | TAS                          |
|------------|------------------------------|
| Version(s) | <b>3.0.0</b><br><b>4.0.0</b> |

### Why Should I Be Concerned About This Change?

The BOSH System Metrics Forwarder is removed from TAS for VMs

### How Can I Tell If I'm Impacted?

You are impacted if you have been using the deprecated BOSH System Metrics Server and Forwarder. You are using the BOSH System Metrics Server if you have selected the “Enable BOSH System Metrics Server (deprecated)” option in the Ops Manager Director product configuration.

### What Should I Do About It?

To continue receiving system metrics, you must select the “Enable System Metrics” checkbox in the Director Config pane of the BOSH Director tile.

To avoid deployment, platform automation, or data collection failures, you must update any queries that reference `bosh-system-metrics-forwarder` as the `source_id` for metrics to reference `system_metrics_agent` instead.

Additionally, metric names now include underscores instead of periods. For example, the metric named `system.cpu.sys` in previous versions of TAS for VMs is named `system_cpu_sys` in TAS for VMs v3.0.

### Background

BOSH System Metrics Server and Forwarder are deprecated in favor of System Metrics server and scraper.

### Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-operations-manager/3-0/tanzu-ops-manager/release-notes.html#bosh-system-metrics-server-is-removed-19>

## HAProxy removed

### Why Should I Be Concerned About This Change?

If your environment was running an HAProxy instance group, you must reconfigure your networking configurations or else will get a deployment error when upgrading to TAS 3.0.

### How Can I Tell If I'm Impacted?

To check if you are running HAProxy, open the Networking tab in Ops Manager. Under the field “Routing TLS Termination”, you’ll see “HAProxy”.

### What Should I Do About It?

Change your networking and resource configurations to point directly to Gorouter. Full directions are in the “HAProxy Removed” doc above.

### Background

HAProxy was previously supported as an instance group in front of gorouter in order to support features not offered by gorouter. Now that gorouter supports TLS termination, HAProxy is no longer needed.

## Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#haproxy-removed>
- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/frontend-idle-timeout.html>

## Log Cache nozzle ingress removed

### Versions Introduced

| Product    | TAS   |
|------------|-------|
| Version(s) | 3.0.0 |
|            | 4.0.0 |

### Why Should I Be Concerned About This Change?

From TAS 3.0.0 Log Cache uses syslog ingress, and the option to use nozzle ingress has been removed.

### How Can I Tell If I'm Impacted?

You are impacted if you have not checked the “Enable Log Cache syslog ingestion” option, or set the corresponding `.properties.enable_log_cache_syslog_ingestion` product property to `false`. From TAS 3.0.0 this is no longer a supported configuration.

In addition Diego Cells with high logging volume might experience higher CPU usage than they did prior to this change.

### What Should I Do About It?

Confirm that your instances, including those within isolation segments, are permitted to establish connections to Log Cache nodes on port 6067. You may need to update firewall rules to allow logs to flow directly from your instances to the Log Cache syslog server.

Consider scaling your Diego Cells if you have applications with high logging volume due to the increased load from the syslog agent on the Diego Cell.

### Background

Log Cache ingestion via the Reverse Log Proxy (RLP) has been removed.

## ActiveLocks removed from Key Performance Indicators

### Why Should I Be Concerned About This Change?

If you were monitoring `ActiveLocks` on your environment, upgrading to TAS 3.0.0 will increase your metric by 1.

## How Can I Tell If I'm Impacted?

You are impacted if your environment Key Performance Indicators includes Locket [ActiveLocks](#).

## What Should I Do About It?

Remove this metric from any KPI monitoring you maintain.

### Background

[ActiveLocks](#) is a metric emitted by Locket, a distributed locking service used by multiple services in CloudFoundry. With the introduction of a new, opt-in service that uses Locket, the expected number of active locks increased by 1. Our community noted that a feature-dependent was a smell of a bad performance indicator; while the information is useful in debugging, it is not useful as a performance indicator and we no longer recommend monitoring it as an environment health metric.

### Links

## cflinuxfs4 as default stack may cause failures to push apps

### Why Should I Be Concerned About This Change?

cflinuxfs3 (backed by Ubuntu Bionic) has been deprecated in favor of cflinuxfs4 (backed by Ubuntu Jammy). If apps are configured to use the latest stack, upgrading TAS will upgrade app stacks and may cause a push failure.

## How Can I Tell If I'm Impacted?

You can see what stack your apps are configured to use by running:

```
cf audit-stack
```

If apps are followed by [cflinuxfs3](#), they are running an outdated stack.

## What Should I Do About It?

You should re-stage your app to use [cflinuxfs4](#).

```
cf push <APP_NAME> -s cflinuxfs4
```

Resolve any push errors prior to upgrading TAS. This may entail updating the buildpack that your app uses. If fixing app staging is not possible before the TAS upgrade you can configure apps to run on [cflinuxfs3](#) as a temporary workaround.

### Background

“Stacks” are the pre-built root file system that Cloud Foundry uses to create app containers. Keeping these up-to-date with operating system updates is key to updating security vulnerabilities and other issues.

## Links

- [Managing apps and their stacks](#)
- [TAS cflinuxfs4 Migration Proposal](#) discusses stack change behaviors for each TAS release

## Diego and Routing Components More Strict With TLS Protocols

### Versions Introduced

| Product    | TAS            |
|------------|----------------|
|            | <b>2.11.27</b> |
| Version(s) |                |
|            | <b>2.12.28</b> |
|            | <b>2.13.13</b> |

### Why Should I Be Concerned About This Change?

Diego and Routing components have been updated to be more strict with TLS protocols. External services and databases, end users, and services making requests to gorouter should be using TLS 1.2 and have certs signed with a newer hash than SHA-1, or else they will experience TLS errors.

### How Can I Tell If I'm Impacted?

For services talking to Diego components, if your environment is impacted they will not be able to successfully make a connection to Diego. For external users services talking to gorouter, you should see TLS errors in your access logs.

If you are using an external database, Diego will throw errors trying to start processes like Locket and BBS.

You can check the Signature Algorithm of your external database and external services with the following command:

```
echo '' | openssl s_client -connect <HOSTNAME>:<PORT> -servername
<HOSTNAME> 2>/dev/null | openssl x509 -noout -text | grep
'Signature Algorithm'
```

You can check that TLS 1.2 is supported with the following command:

```
echo openssl s_client -connect google.com:443 -servername google.com
-tls1_2 || echo "TLS 1.2 unsupported"
```

If you see no output, TLS 1.2 is supported. If you see the TLS 1.2 unsupported message, it is unsupported and will need to be updated.

### What Should I Do About It?

Make sure that services talking to your Diego components and services talking to gorouter are not using TLS 1.0 or 1.1, or using SHA-1 certificates.

### Background

Diego and Routing components, including gorouter, use an up-to-date version of Golang. As of Golang 1.18, TLS requirements have been made more strict in two major ways. First, TLS 1.0 and 1.1 disabled in favor of TLS 1.2. Second, crypto/x509 will now reject certificates signed with the SHA-1 hash function. See Golang release notes for details.

## Links

- <https://tip.golang.org/doc/go1.18>

## Breaking changes if you are starting from TAS for VMs v2.12

### Logging stricter IP address parsing

#### Versions Introduced

| Product    | TAS     | Isolation Segment | TAS Windows |
|------------|---------|-------------------|-------------|
| Version(s) | 2.11.14 | 2.11.10           | 2.11.10     |
|            | 2.12.7  | 2.12.4            | 2.12.5      |
|            | 2.13.0  | 2.13.0            | 2.13.0      |
|            | 3.0.0   | 3.0.0             | 3.0.0       |
|            | 4.0.0   | 4.0.0             | 4.0.0       |

#### Why Should I Be Concerned About This Change?

Logging components provided by loggregator-agent-release and syslog-release have been upgraded to Go 1.17.

From Go 1.17 the treatment of IP addresses is stricter and any IP addresses where an octet starts with a leading zero is now invalid.

#### How Can I Tell If I'm Impacted?

Review your configured application syslog drains and the address of any configured syslog destination in the TAS “System Logging” tab. If your configuration contains an IP address with an octet that has a leading zero then you are impacted.

#### What Should I Do About It?

Modify your configuration to express the ip address without a leading zero.

#### Background

The Go Developers chose to disallow IP addresses with octets with leading zeros due to them presenting a security concern.

## Links

- <https://go.dev/doc/go1.17>

## System metrics scrape frequency increased

Versions Introduced

| Product    | TAS                                          |
|------------|----------------------------------------------|
| Version(s) | 2.11.8<br>2.12.1<br>2.13.0<br>3.0.0<br>4.0.0 |

### Why Should I Be Concerned About This Change?

The frequency with which system metrics are scraped increased from a fixed frequency of every 1 minute to a configurable default of every 15 seconds. This may cause increased load on your logging and metrics infrastructure.

### How Can I Tell If I'm Impacted?

If you have enabled system metrics in the Ops Manager director config and you are upgrading to a version of TAS after the versions that introduced this change then you are impacted.

You are not impacted if you are using the deprecated BOSH system metrics server instead of the recommended system metrics scraper.

### What Should I Do About It?

The default 15 second scrape frequency is recommended. You may not need to take action if your logging and metrics infrastructure is already scaled sufficiently to handle the increased number of metrics. Aside from scaling another option is to reduce the scrape frequency.

The scrape interval can be changed by modifying the `.properties.system_metrics_scraper_scrape_interval` TAS property. This property is configurable within Ops Manager under the System Logging tab as “System metrics scrape interval”.

### Background

Prior to the versions that this change was introduced the system metrics scrape interval was hard-coded to every 1 minute.

## Jobs Error interface changes in Rails 6

### Why Should I Be Concerned About This Change?

Changes internal to the Cloud Controller worker may cause `cf push` downtime during upgrade.

## How Can I Tell If I'm Impacted?

You have a significant (>100) number of `cloud_controller_worker` VMs.

## What Should I Do About It?

While there is an existing mitigation in place, it may not be sufficient for large foundations which might still experience downtime when running cf push. Please see [https://github.com/cloudfoundry/cloud\\_controller\\_ng/issues/2748](https://github.com/cloudfoundry/cloud_controller_ng/issues/2748) for more details

## Background

Rails 6 introduced a new interface for the Error class, which means Rails 5 servers cannot de-serialize the new Error class. CAPI release in TAS 2.13 contains upgrade of Ruby on Rails dependencies to Ruby on Rails 6.1 (from Ruby on Rails 5).

While upgrading Cloud Controller VMs to this release, new jobs created by API servers containing the Rails 6 upgrade may serialize the new Errors interface in the database as part of jobs for the Worker VMs to pick up. Worker VMs which have not upgraded, and are still running Cloud Controller with Rails 5, will fail to de-serialize the Error class's new interface.

## Links

- [https://github.com/cloudfoundry/cloud\\_controller\\_ng/issues/2748](https://github.com/cloudfoundry/cloud_controller_ng/issues/2748)

## cf CLI v6 not supported in 2.13

### Why Should I Be Concerned About This Change?

TAS for VMs v2.13 does not support cf CLI v6; this means that cf CLI v6 and TAS for VMs v2.13 and later are not tested together, and if you or your users encounter issues using the v6 CLI, you will need to upgrade to v7 to get effective support.

The change from cf CLI v6 to v7 (and v7 to v8) is itself a major version bump, with its own breaking changes.

Two examples:

1. the flags supported by cf push have changed, See the articles on Upgrading for more details.
2. the way quota is counted for staging apps is more conservative, and this can cause push failures. See the linked KB for details.

### How Can I Tell If I'm Impacted?

If any automation or clients targeting the platform (especially app developer pipelines, or custom service brokers) that have not already explicitly updated to cf CLI version v7 or greater.

### What Should I Do About It?

Your users must upgrade to cf CLI v7 or cf CLI v8. To upgrade to a supported cf CLI version, see Upgrading to cf CLI v7 or Upgrading to cf CLI v8.

## Background

The newer versions of the CF cli target the new v3 version of the Cloud Controller API. The cf CLI v6 relies on the deprecated v2 Cloud Controller API, which may be entirely removed in a future TAS version line.

## Links

- [TAS 2.13 Breaking Changes of CLI Release Note](#)
- [Upgrading to cf CLI v7](#)
- [Upgrading to cf CLI v8](#)

## Log Cache Uses Its Own Instance Group

### Why Should I Be Concerned About This Change?

As of TAS for VMs v2.13, the Log Cache component runs on its own Log Cache instance group, and is no longer deployed on Doppler instances. Operators should ensure they scale Log Cache appropriately.

### How Can I Tell If I'm Impacted?

You are impacted if you are upgrading to TAS 2.13.0 or higher.

### What Should I Do About It?

Scale up your Log Cache instance count. VMware recommends scaling up to match the number of VMs and amount of memory as your Doppler instances before the upgrade. Starting larger and then adjusting for actual use is safer than a deployment failure.

You can also consider reducing the memory allocation for Doppler instances now that Log Cache is no longer deployed there.

## Background

Separating Log Cache out to its own instance group allows it to be scaled independently of Dopplers and Traffic Controllers. For example, to provide more memory for storing logs and metrics.

## Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#log-metric-topology>
- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#separate-log-cache>

## Log Cache uses syslog ingress by default

### Why Should I Be Concerned About This Change?

The logging Metric topology has been changed. From TAS 2.13.0 Log Cache uses syslog ingress by default.

### How Can I Tell If I'm Impacted?

You may be impacted if you are not seeing logs and metrics from Diego Cells deployed by TAS or the Isolation Segment or Tanzu Application Service for VMs [Windows] products.

In addition Diego Cells with high logging volume might experience higher CPU usage than they did prior to this change.

### What Should I Do About It?

Confirm that your instances, including those within isolation segments, are permitted to establish connections to Log Cache nodes on port 6067. You may need to update firewall rules to allow logs to flow directly from your instances to the Log Cache syslog server.

Consider scaling your Diego Cells if you have applications with high logging volume due to the increased load from the syslog agent on the Diego Cell.

During the upgrade Diego Cells may receive the new Log Cache BOSH DNS name `log-cache.service.cf.internal` and attempt to send logs and metrics over syslog. VMware recommends upgrading to at least the following patch versions prior to the upgrade and additionally re-deploying the Isolation Segment and TAS for VMs [Windows] products so that the new Log Cache BOSH DNS name is resolvable.

- TAS for VMs v2.11.16
- TAS for VMs v2.12.9

### Background

As of TAS for VMs v2.13, the Log Cache component runs on its own Log Cache instance group, and is no longer deployed on Doppler instances. In addition, syslog ingestion was set as the default for Log Cache to use industry standard protocols.

### Links

- <https://techdocs.broadcom.com/us/en/vmware-tanzu/platform/tanzu-platform-for-cloud-foundry/4-0/tpcf/runtime-rn.html#log-metric-topology>

## Service instance metrics might not be retrievable using the Log Cache cf CLI plugin

### Why Should I Be Concerned About This Change?

Service instance metrics might not be retrievable using the Log Cache cf CLI plugin.

### How Can I Tell If I'm Impacted?

If you use the Log Cache cf CLI plugin to retrieve service instance metrics and your service tiles use log cache syslog ingestion you will be impacted.

### What Should I Do About It?

If you need to retrieve metrics from service tiles that do not support this feature:

- upgrade to a version of the service tile that allows for syslog ingestion OR
- for TAS 2.13 only, deactivate the Enable Log Cache syslog ingestion checkbox in the System Logging pane of the TAS for VMs tile. The associated product property is: `.properties.enable_log_cache_syslog_ingestion`. Note that this is a temporary solution, as this setting is no longer available in TAS 3.0.0.

### Background

As of TAS for VMs v2.13, the Log Cache component runs on its own Log Cache instance group, and is no longer deployed on Doppler instances. In addition, syslog ingestion was set as the default for Log Cache.

## Traffic Controller unavailable during upgrade

### Why Should I Be Concerned About This Change?

V1 firehose nozzles such as the Splunk Nozzle for VMware Tanzu may fail to connect to the firehose during an upgrade.

### How Can I Tell If I'm Impacted?

You will be impacted during the upgrade if both of the following are true:

- You have a V1 firehose nozzle deployed
- You upgrading to TAS v2.13.0 - v2.13.12 or TAS 3.0.0 - 3.0.2

### What Should I Do About It?

VMware recommends that you upgrade to a more recent version of TAS that does not have this issue.

### Background

The Traffic Controller component which V1 nozzles connect to had previously blocked on startup until Log Cache was available. In TAS 2.13 Log Cache was separated out to a separate instance group meaning that Traffic Controller blocks and is unavailable until the new Log Cache instances become available.

## Golang 1.17 Rejects IPv4 Addresses With Leading Zeros

### Why Should I Be Concerned About This Change?

If you have IPv4 addresses that contain decimal components leading zeros, (ie 192.168.020.100) you will receive a deploy error. You will need to reformat your IP (192.168.20.100) and deploy again.

### How Can I Tell If I'm Impacted?

This affects properties that feed into all releases that use Golang v1.17. If impacted, you will receive Bosh templating errors during deploy.

### What Should I Do About It?

Operators can remove the leading zeros and try deploying again.

### Background

From Golang release notes: The ParseIP and ParseCIDR functions in Golang's net library now reject IPv4 addresses which contain decimal components with leading zeros. These components were always interpreted as decimal, but some operating systems treat them as octal. This mismatch could hypothetically lead to security issues if a Go application was used to validate IP addresses which were then used in their original form with non-Go applications which interpreted components as octal.

## Gorouter Certificates Require a SAN Extension

### Why Should I Be Concerned About This Change?

Routing-release keeps up-to-date with Golang, and Golang 1.17 requires certs to include a Subject Alternative Name (SAN). (This is an enforcement of a deprecation that was introduced in Golang 1.15). If any certificates for services that terminate TLS connections in Gorouter lack a SAN, clients cannot connect to servers and deployment fails. External systems that the Gorouter connects must also have certificates with a valid SAN, or else requests experience a failed TLS handshake.

### How Can I Tell If I'm Impacted?

For all certs in Ops Manager, copy the cert text to a file and decode it with the following command to see if it contains a SAN:

```
openssl x509 -noout -text -in [FILE]
```

Follow this same process for certs on external services that gorouter connects to. See the Knowledge Base article above for detailed instructions.

### What Should I Do About It?

If any certs do not contain a SAN, you must rotate certs with a newly-generated cert that contains a SAN. See the Ops Manager documentation above.

### Background

Golang's `crypto/x509` library uses certs to verify the server or client hostname. In the past, operators could use the Common Name field to input hostname; as of Golang 1.15, the Common Name field has been deprecated for hostname verification and the Subject Alternative Name must be provided to verify hostname.

## Gorouter sends all responses with transfer-encoded chunks

### Versions Introduced

| Product    | TAS                            |
|------------|--------------------------------|
| Version(s) | <b>2.11.3</b><br><b>2.13.0</b> |

### Why Should I Be Concerned About This Change?

If your clients or proxies that access apps cannot handle a chunked response, or expect a Content-Length header, they will break.

### How Can I Tell If I'm Impacted?

One common symptom is that applications now return duplicate Transfer-Encoding headers, and gorouter logs error "too many transfer encodings".

### What Should I Do About It?

Fix your clients to be able to handle a chunked response.

### Background

Previous versions of TAS may, for short responses, silently remove the Transfer encoding header and replace it with a Content Length header. This convenience was dependent on Golang 1.15 and lead to a false sense of mitigation.

Golang 1.16 now prioritizes flushing partial requests to the client and no longer changes the response to not be chunked.

## Breaking changes if you are starting from TAS for VMs v2.11

### Log Cache aggregate drain metadata missing

#### Why Should I Be Concerned About This Change?

TAS 2.11.16 moved aggregate drain configuration to the syslog binding cache to improve deploy speed. Dependent on your configuration this could cause the Smoke Test errand to fail.

#### How Can I Tell If I'm Impacted?

You are impacted if “Enable Log Cache syslog ingestion” is checked and “Default loggregator drain metadata” is unchecked and you attempt to upgrade to a version of TAS from 2.11.16 - 2.11.21.

The corresponding product properties are

- .properties.enable\_log\_cache\_syslog\_ingestion
- .properties.default\_loggregator\_drain\_metadata

#### What Should I Do About It?

Upgrade to TAS 2.11.22 or greater.

## Background

Operators may configure aggregate drains to send all application logs to a syslog destination. The same mechanism may be used within TAS to populate Log Cache. If metadata is not enabled for the Log Cache aggregate drain then Log Cache will not have the metadata expected to function correctly.

## Minimize user downtime when upgrading from 2.11 to 2.12

## Why Should I Be Concerned About This Change?

To minimize downtime for developers pushing apps, upgrade from TAS for VMs v2.11.9 or later. Upgrading from earlier patch versions can result in an Unknown Error when pushing apps.

## How Can I Tell If I'm Impacted?

Your current version of TAS is 2.11.0 through 2.11.8.

## What Should I Do About It?

You should upgrade to TAS 2.11.9 or higher before upgrading to 2.12 or higher.

## Background

Cloud Controller in affected versions has chance that app lifecycle\_type could be nil when determining app lifecycle.

## Envoy advertises HTTP2 support over ALPN

### Why Should I Be Concerned About This Change?

If applications do not support HTTP/2 when using Container to Container (C2C) communication through the Envoy proxy (ports 61001 or 61443), requests between these apps will fail.

### How Can I Tell If I'm Impacted?

If you are using container to container networking, and have network policies allowing apps to talk to other apps on ports 61001 or 61443, you may be affected.

Use the cf network-policies command to list policies, and look for those ports.

### What Should I Do About It?

Investigate the destination applications for these policies, to determine if they support HTTP/2 requests. If not, the client applications will need to be updated to negotiate down to HTTP/1.1 when making their requests.

## Background

- ALPN is the Application-Layer Protocol Negotiation, which allows HTTP connections to negotiate what protocols are supported.
- Envoy is a proxy sitting alongside each application container to facilitate TLS termination.

## Zipkin Trace-ID Now 16 Bytes

### Versions Introduced

| Product    | TAS            |
|------------|----------------|
| Version(s) | <b>2.11.10</b> |
|            | <b>2.12.6</b>  |

### Why Should I Be Concerned About This Change?

There is a chance that your apps are not capable of processing the longer 8-byte Trace-ID header. If so, you may receive 400-level errors after gorouter forwards requests to your app.

### How Can I Tell If I'm Impacted?

Foundations that do not enable Zipkin are not affected. To see if zipkin is enabled, look at the Networking tab of the TAS tile in Ops Manager, and see if Enable Zipkin is checked.

If Zipkin is enabled, applications incompatible with this change will throw errors in their application or access logs, related to Zipkin header length.

### What Should I Do About It?

The header size was increased from 8-bytes to 16-bytes in accordance to the W3 standard; you must update your app to be able to handle 16-byte request headers.

### Background

Zipkin is a library that allows users to trace a request through multiple components, with the help of a Trace-ID that is the same for the lifecycle of one request. Having a longer Trace-ID is in compliance with W3 standards and also decreases the chance of generating duplicate IDs.

### Links

- <https://zipkin.io/pages/instrumenting.html>
- <https://www.w3.org/TR/trace-context/#trace-id>
- [https://docs.cloudfoundry.org/adminguide/zipkin\\_tracing.html](https://docs.cloudfoundry.org/adminguide/zipkin_tracing.html)

After these changes are handled, continue reading the next sections.

## VMware Tanzu Application Service for Windows v6.0 Release Notes

These are the release notes for VMware Tanzu Application Service for VMs [Windows] (TAS for VMs [Windows]) v6.0.

Because VMware uses the Percona Distribution for MySQL, expect a time lag between Oracle releasing a MySQL patch and VMware releasing TAS for VMs [Windows] containing that patch.

Before you install the tile, review the [Windows Stemcell Compatibility Matrix](#).

Windows Stemcell v2019.79 has been removed from Broadcom Support because of an incompatibility found in the Windows Updates included and the `winc` component used in the Tanzu Platform for Cloud Foundry Windows. This issue has been fixed in TAS for VMs [Windows] v6.0.11. For details, see [Tanzu Platform for Cloud Foundry on Windows - Nov 2024 Stemcell \(2019.79\) Issue Causing Stuck/Hung BOSH Deployments on Windows Diego Cells](#) in the Broadcom Support KB.

---

**Deprecation Notice:** Cloud Foundry Command-Line Interface (cf CLI) v7 is deprecated and will lose support. For how to upgrade to cf CLI v8 see [Upgrading to cf CLI v8](#).

## Releases

### 6.0.18

**Release Date:** 07/22/2025

- Bump diego to version [2.118.0](#)
- Bump envoy-nginx to version [0.46.0](#)
- Bump garden-runc to version [1.73.0](#)
- Bump hwc-offline-buildpack to version [3.1.78](#)
- Bump winc to version [2.39.0](#)
- Bump windowsfs-release to version [2.85.0](#)

| Component             | Version | Release Notes |
|-----------------------|---------|---------------|
| windows2019 stemcell  | 2019.87 |               |
| count-cores-indicator | 2.0.0   |               |

| Component | Version | Release Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 6.0.16

**Release Date:** 05/15/2025

- Bump diego to version [2.117.0](#)
- Bump envoy-nginx to version [0.43.0](#)
- Bump garden-runc to version [1.71.0](#)
- Bump hwc-offline-buildpack to version [3.1.67](#)
- Bump loggregator-agent to version [8.3.8](#)
- Bump winc to version [2.36.0](#)
- Bump windowsfs-release to version [2.83.0](#)

## 6.0.15

**Release Date:** 04/15/2025

- **[Feature]** There is a new “Enable container network traffic metrics for app instances” property in the “Networking” tab
- Bump envoy-nginx to version [0.42.0](#)
- Bump hwc-offline-buildpack to version [3.1.61](#)
- Bump loggregator-agent to version [8.3.7](#)
- Bump otel-collector to version [0.11.4](#)
- Bump winc to version [2.35.0](#)
- Bump windows-syslog to version [1.3.8](#)
- Bump windowsfs-release to version [2.82.0](#)

### Security Fixes

The following table lists CVEs that were fixed in each TAS for VMs [Windows] component since the previous patch version of TAS for VMs [Windows]:

| Component         | Vulnerabilities Resolved                                                                                                                                                                                                                            |

| smoke-tests           | 4.10.0  |
| winc                  | 2.34.0  |
| windows-syslog        | 1.3.6   |
| windows-utilities     | 0.20.0  |
| windowsfs-release     | 2.80.0  |

## 6.0.13

**Release Date:** 03/11/2025

- **[Feature Improvement]** Operators can now let Puma auto-configure the number of workers based on the number of available cores.
- **[Feature Improvement]:** Backport GA OpenTelemetry Collector
- Bump envoy-nginx to version 0.39.0
- Bump garden-runc to version 1.70.0
- Bump hwc-offline-buildpack to version 3.1.56
- Bump loggregator-agent to version 8.3.5
- Bump windows-syslog to version 1.3.6
- Bump windowsfs-release to version 2.79.0

## Security Fixes

The following table lists CVEs that were fixed in each TAS for VMs [Windows] component since the previous patch version of TAS for VMs [Windows]:

| <b>Component</b>  | <b>Vulnerabilities Resolved</b>                                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loggregator-agent | <ul style="list-style-type: none"> <li>• <a href="#">CVE-2024-45341</a></li> <li>• <a href="#">CVE-2024-45336</a></li> <li>• <a href="#">CVE-2025-22866</a></li> </ul> |

## 6.0.12

**Release Date:** 02/03/2025

- **[Feature Improvement]** Add optional, experimental pprof extension to OTel Collector
- Bump envoy-nginx to version [0.34.0](#)
- Bump garden-runc to version [1.67.0](#)
- Bump hwc-offline-buildpack to version [3.1.52](#)
- Bump loggregator-agent to version [8.3.3](#)
- Bump otel-collector to version [0.11.2](#)

- Bump winc to version [2.34.0](#)
- Bump windows-syslog to version [1.3.5](#)
- Bump windowsfs-release to version [2.77.0](#)

## Security Fixes

The following table lists CVEs that were fixed in each VMware Tanzu Application Service for VMs [Windows] component since the previous patch version of VMware Tanzu Application Service for VMs [Windows]:

| Component         | Vulnerabilities Resolved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 6.0.11

**Release Date:** 01/09/2025

- Bump envoy-nginx to version 0.33.0
- Bump garden-runc to version 1.64.0
- Bump hwc-offline-buildpack to version 3.1.40
- Bump loggregator-agent to version 8.3.2
- Bump winc to version 2.32.0
- Bump windows-syslog to version 1.3.4
- Bump windowsfs-release to version 2.76.0

## Security Fixes

The following table lists CVEs that were fixed in each VMware Tanzu Application Service for VMs [Windows] component since the previous patch version of VMware Tanzu Application Service for VMs [Windows]:

| Component         | Vulnerabilities Resolved                                                                                                                                                                                                                                                                                                               |

## 6.0.9

**Release Date:** 10/07/2024

- Bump diego to version [2.105.0](#)
- Bump envoy-nginx to version [0.29.0](#)
- Bump garden-runc to version [1.57.0](#)
- Bump hwc-offline-buildpack to version [3.1.39](#)
- Bump winc to version [2.29.0](#)
- Bump windowsfs-release to version [2.72.0](#)

## 6.0.8

**Release Date:** 09/27/2024

- **[Bug Fix]** Fixes a bug preventing TCP Routing from working on IST/TASW tiles when the TAS Routing API Endpoint Protocol is configured to be HTTPS only
- Bump diego to version 2.103.0
- Bump envoy-nginx to version 0.27.0
- Bump garden-runc to version 1.56.0
- Bump loggregator-agent to version 8.2.1
- Bump otel-collector to version 0.10.1
- Bump winc to version 2.28.0
- Bump windows-syslog to version 1.3.3
- Bump windowsfs-release to version 2.71.0

## 6.0.7

**Release Date:** 08/22/2024

### Caution

If you are upgrading from v6.0.5 or v6.0.6 to a later patch version, upgrade TAS for VMs and apply those changes before you upgrade TAS for VMs [Windows]. Failure to upgrade TAS for VMs first will result in TCP route outages on TAS for VMs [Windows].

For more information, see [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#) in the Broadcom Support Knowledge Base.

- **[Bug Fix]** Fixes known issue [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#)
- Bump diego to version [2.102.0](#)
- Bump envoy-nginx to version [0.26.0](#)
- Bump garden-runc to version [1.54.0](#)
- Bump loggregator-agent to version [8.1.5](#)
- Bump otel-collector to version [0.7.0](#)
- Bump winc to version [2.26.0](#)
- Bump windows-syslog to version [1.3.2](#)
- Bump windowsfs-release to version [2.68.0](#)

## 6.0.6

Release Date: 07/29/2024

### Caution

If you are upgrading from v6.0.5 or v6.0.6 to a later patch version, upgrade TAS for VMs and apply those changes before you upgrade TAS for VMs [Windows]. Failure to upgrade TAS for VMs first will result in TCP route outages on TAS for VMs [Windows]. For more information, see [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#) in the Broadcom Support Knowledge Base.

- **[Bug Fix]** Adds 2 minute caching for failed dns lookups in syslog agent to avoid dns load for malformed drain urls.
- **[Feature]** Adds `PrometheusRemoteWrite` exporter and `batch` processor.
- Bump hwc-offline-buildpack to version `3.1.38`
- Bump loggregator-agent to version `8.1.3`
- Bump otel-collector to version `0.6.0`

- Bump windows-syslog to version 1.3.1

## 6.0.5

### Caution

If you are upgrading from v6.0.5 or v6.0.6 to a later patch version, upgrade TAS for VMs and apply those changes before you upgrade TAS for VMs [Windows]. Failure to upgrade TAS for VMs first will result in TCP route outages on TAS for VMs [Windows].

For more information, see [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#) in the Broadcom Support Knowledge Base.

**Release Date:** 07/08/2024

- Bump diego to version [2.100.0](#)
- Bump otel-collector to version [0.5.0](#)
- Bump winc to version [2.25.0](#)
- Bump windowsfs-release to version [2.67.0](#)

## 6.0.4

**Release Date:** 05/29/2024

- **[Bug Fix]** Remove replication-canary
- Bump diego to version [2.99.0](#)
- Bump garden-runc to version [1.53.0](#)

| garden-runc | 1.53.0  | <p>▼ v1.53.0</p> <pre> ## Changes - **DEPRECATION NOTICE** The `garden.experimental_use_containerd_mode_for_processes` property and usage of Garden when run in containerd mode for processes is now deprecated and no longer tested. - **DEFAULT CHANGE** - The default mode for garden containers is now containerd. This has been the default in cf-deployment since 2018. - **REMOVAL OF EXPERIMENTAL FUNCTIONALITY NOTICE** The experimental option to run the garden server process in rootless mode has been removed, as it did not work as expected and was an abandoned feature. - Go package dependency bumps ## Bosh Job Spec changes: ``` diff --git a/jobs/garden-binaries/spec b/jobs/garden-binaries/spec index 0433639a..a8a96bae 100644 --- a/jobs/garden-binaries/spec +++ b/jobs/garden-binaries/spec @@ -15,7 +15,6 @@ packages: - grootfs - xfs-progs - thresholder - - netplugin-shim - dontpanic - tini diff --git a/jobs/garden/spec b/jobs/garden/spec index 027df351..093e53e1 100644 --- a/jobs/garden/spec +++ b/jobs/garden/spec @@ -36,7 +36,6 @@ packages: - grootfs - xfs-progs - thresholder - - netplugin-shim - dontpanic - tini @@ -199,10 +198,6 @@ properties: description: AppArmor profile to use for unprivileged container processes default: garden-default - garden.experimental_rootless_mode: -   description: A boolean stating whether or not to run garden-server as a non-root user -   default: false - # We believe this defaults to false to help concourse: https://github.com/cloudfoundry/garden-runc-release/releases/tag/v1.5.0 </pre> |

## 6.0.2

**Release Date:** 05/01/2024

- **[Bug Fix]** Windows syslog forwarder handles case when remote syslog endpoints are unavailable by backing off and eventually restarting.
- Bump diego to version 2.98.0
- Bump envoy-nginx to version 0.25.0
- Bump garden-runc to version 1.52.0
- Bump hwc-offline-buildpack to version 3.1.36
- Bump loggregator-agent to version 8.1.0
- Bump windows-syslog to version 1.3.0
- Bump windowsfs-release to version 2.66.0

| loggregator-agent | 8.1.0   | <p>▼ v8.1.0</p> <pre> ## What's Changed * Replace usages of `grpc.Dial` with `grpc.NewClient` which does not open connections until necessary * Bump dependencies ### Experimental OTel Collector changes * Added `temporary_emit_otel_traces` property to the loggr-forwarder-agent and loggr-forwarder-agent-windows jobs. Setting this property to `true` activates conversion of appropriately tagged http timers to OpenTelemetry traces (it defaults to `false`). See cloudfoundry/gorouter#407. **Full Changelog**: <a href="https://github.com/cloudfoundry/loggregator-agent-release/compare/v8.0.3...v8.1.0">https://github.com/cloudfoundry/loggregator-agent-release/compare/v8.0.3...v8.1.0</a> </pre> <p>▼ v8.0.4</p> <pre> Don't use. It contains the code changes from v8.1.0 but without a semver minor bump to indicate new functionality. </pre> |
| otel-collector    | 0.4.1   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 6.0.0

Release Date: 04/09/2024

- **[Breaking Change]** Replace cpu entitlement counters with cpu\_entitlement percentage gauge
- **[Breaking Change]** Remove (deprecated) Metrics Agent and Metrics Discovery Release
- **[Feature]** Add support for NTLM authentication in Gorouter
- **[Feature]** Adds Diego support for Docker workloads using OCI images
- **[Feature]** Expose a custom environment identifier on component logs forwarded via syslog
- **[Feature Improvement]** OTel Collector marks OTLP Sums as monotonic if they originate from a Loggregator counter
- **[Feature Improvement]** Garden now emits an `UnkillableContainers` metric to help identify cells that will be unable to redeploy successfully without operator intervention
- **[Feature Improvement]** Make database “encrypt key” setting more intentional, to avoid password-manager autofilling of the field
- **[Feature Improvement]** Reintroduce global log rate limit
- **[Feature Improvement]** A more useful error is now thrown if the (windows) stemcell has not been configured with the necessary CCG support.

## How to Upgrade

The TAS for VMs [Windows] v6.0 tile is available with the release of VMware Tanzu Application Service for VMs (TAS for VMs) v6.0. To use the TAS for VMs [Windows] v6.0 tile, you must install VMware Tanzu Operations Manager v2.10 or later and TAS for VMs v6.0 or later.

## New Features in TAS for VMs [Windows] v6.0

TAS for VMs [Windows] v6.0 includes the following major feature:

### Reintroduction of global log rate limit

TAS v3.0 introduced granular app log rate limits for fine-grained control over application log rates.

TAS for VMs [Windows] v4.0 removed the older global log rate limit feature **App log rate limit (deprecated)** under **App Containers**. This was problematic for operators who were performing a jump upgrade to TAS for VMs [Windows] v4.0 (skipping v3.0), as logs would not be rate limited until application-based log rate limits were applied.

TAS for VMs [Windows] v6.0 restores the global log rate limit, so that operators can perform upgrades while retaining log rate limits. Operators must configure the same setting separately for both VMware Tanzu Application Service for VMs and Isolation Segment.

If you had previously set a global log rate limit, this limit is re-applied following the upgrade to TAS for VMs [Windows] v6.0.

## Breaking changes

TAS for VMs [Windows] v6.0 includes the following breaking changes:

## Known issues

There are no known issues for TAS for VMs [Windows] v6.0.

## Isolation Segment v6.0 Release notes

Here you will find the release notes for Isolation Segment v6.0.

VMware Tanzu Application Service for VMs (TAS for VMs) is certified by the Cloud Foundry Foundation for 2023.

For more information about the Cloud Foundry Certified Provider Program, see [How Do I Become a Certified Provider?](#) on the Cloud Foundry website.

Because VMware uses the Percona Distribution for MySQL, expect a time lag between Oracle releasing a MySQL patch and VMware releasing TAS for VMs containing that patch.

---

**Deprecation Notice:** Cloud Foundry Command-Line Interface (cf CLI) v7 is deprecated and will lose support. For how to upgrade to cf CLI v8 see [Upgrading to cf CLI v8](#).

For release 6.0.0 to 6.0.3, CVE-2024-22279. (VMware Tanzu Application Service for VMs GoRouter contains an RFC protocol issue that can lead to a denial of service) has been fixed. For details, see [TNZ-2024-0100](#).

## Releases

### 6.0.18

**Release Date:** 07/22/2025

- **[Bug Fix]** Pick correct rootfs for sidecar containers
- Bump cf-networking to version [3.72.0](#)
- Bump cflinuxfs3 to version [0.642.0](#)
- Bump cflinuxfs4 to version [1.317.0](#)
- Bump diego to version [2.118.0](#)
- Bump garden-runc to version [1.73.0](#)
- Bump nfs-volume to version [7.32.0](#)
- Bump routing to version [0.342.0](#)
- Bump silk to version [3.72.0](#)
- Bump smb-volume to version [3.30.0](#)

### Components

The following table shows the component versions used in this version of Isolation Segment.

| <b>Component</b>          | <b>Version</b> |
|---------------------------|----------------|
| stemcell os: ubuntu-jammy | 1.844          |
| bpm                       | 1.4.20         |
| cf-networking             | 3.72.0         |
| cflinuxfs3                | 0.642.0        |
| cflinuxfs4                | 1.317.0        |
| cf-cli                    | 2.3.0          |
| count-cores-indicator     | 2.0.0          |
| diego                     | 2.118.0        |
| garden-runc               | 1.73.0         |
| loggregator-agent         | 8.3.8          |
| nfs-volume                | 7.32.0         |
| otel-collector            | 0.11.4         |
| routing                   | 0.342.0        |
| silk                      | 3.72.0         |
| smb-volume                | 3.30.0         |
| smoke-tests               | 4.10.0         |
| syslog                    | 12.3.9         |
| tanzu-jammy-stack         | 1.0.1          |

| cf-networking         | 3.72.0  | <p>▼ v3.72.0</p> <pre>## 3.72.0 **Release Date**: June 16, 2025 ## Changes - Dependency Bumps ## Built with go 1.24.4 **Full Changelog**: <a href="https://github.com/cloudfoundry/cf-networking-release/compare/v3.71.0...v3.72.0">https://github.com/cloudfoundry/cf-networking-release/compare/v3.71.0...v3.72.0</a> ## Resources - [Download release 3.72.0 from bosh.io](<a href="https://bosh.io/releases/github.com/cloudfoundry/cf-networking-release?version=3.72.0">https://bosh.io/releases/github.com/cloudfoundry/cf-networking-release?version=3.72.0</a>).</pre> <p>▼ v3.71.0</p> <pre>## 3.71.0 **Release Date**: June 11, 2025 ## Changes - Fixes a bug where policy-server's network-policy list API would break when a user had more than 100 roles in CF. This affected both the `cf network-policies` and `cf remove-network-policy` commands. Thanks @mariash! - Modifies policy-server DB migrations to happen inside the `policy-server` main command, instead of as a pre-start, to remove our reliance on a custom fork of the migration library. Thanks @kart2bc ! - Refactored cni-loader to work with non-deprecated config loading functions. Thanks @kart2bc ! - Bumped to golang 1.24.4 ## Built with go 1.24.4 **Full Changelog**: <a href="https://github.com/cloudfoundry/cf-networking-release/compare/v3.70.0...v3.71.0">https://github.com/cloudfoundry/cf-networking-release/compare/v3.70.0...v3.71.0</a> ## Resources - [Download release 3.71.0 from bosh.io](<a href="https://bosh.io/releases/github.com/cloudfoundry/cf-networking-release?version=3.71.0">https://bosh.io/releases/github.com/cloudfoundry/cf-networking-release?version=3.71.0</a>).</pre> |

#### ▼ v3.29.0

```

## 3.29.0
**Release Date**: July 11, 2025
## Go Package Updates for smbbroker
* Bumped go.mod package 'code.cloudfoundry.
org/tlsconfig' from 'v0.29.0' to 'v0.30.0'
  * Bumped go.mod package 'github.com/google/
pprof' from 'v0.0.0-20250607225305-033d6d78b3

```

## 6.0.16

**Release Date:** 05/15/2025

- Bump bpm to version [1.4.20](#)
- Bump cf-networking to version [3.70.0](#)
- Bump cflinuxfs3 to version [0.630.0](#)
- Bump cflinuxfs4 to version [1.302.0](#)
- Bump cf-cli to version [2.1.0](#)
- Bump diego to version [2.117.0](#)
- Bump garden-runc to version [1.71.0](#)
- Bump loggregator-agent to version [8.3.8](#)
- Bump nfs-volume to version [7.27.0](#)
- Bump routing to version [0.337.0](#)
- Bump silk to version [3.70.0](#)
- Bump smb-volume to version [3.25.0](#)

Component	Version	Release Notes
routing	0.337.0	<p>▼ v0.337.0</p> <pre> ## 0.337.0 **Release Date**: May 07, 2025 ## Changes - gorouter source code has been inlined directly into this release, and the separate repository has been archived. Thank you so much @maxmoehl!!! - Additional request timeout properties have been added to routing-release + gorouter to provide more flexibility with overall request timeouts. Previously `request_timeout_in_seconds` applied to both HTTP/1 and HTTP/2 requests. This limited the ability to guard against slowloris attacks for HTTP/1 requests while also allowing GRPC streams over HTTP/2 to live indefinitely. `request_timeout_in_seconds` is now used as a default value for the new `http_1_request_timeout_in_seconds` and `http_2_request_timeout_in_seconds` properties. See the property descriptions below for more information. Thanks @kart2bc! - Dependency updates ## Bosh Job Spec changes: ``diff diff --git a/jobs/gorouter/spec b/jobs/gorouter/spec index d373561e..a88b19ab 100644 --- a/jobs/gorouter/spec +++ b/jobs/gorouter/spec @@ -523,6 +523,16 @@ properties: Requests from router to backend endpoints that are longer than this duration will be canceled and logged as `backend-request-timeout` errors. If set to 0 this timeout is disabled. default: 900 + http_1_request_timeout_in_seconds: + description:   +   The amount of time HTTP/1 requests from the Gorouter to apps are allowed to live before being canceled. +   Enter value in seconds. syslog	12.3.9	
tanzu-jammy-stack	1.0.1	

## 6.0.15

**Release Date:** 04/15/2025

- **[Feature]** There is a new “Enable container network traffic metrics for app instances” property in the “Networking” tab
- **[Feature Improvement]** Multiple enhancements to Application Security Group data syncing when using Dynamic ASGs at very high scale
- **[Breaking Change]** Gorouter now uses Go 1.24, because of this Gorouter’s limit on 1xx informational responses has changed. It previously aborted a request and returned an error after

receiving more than 5 1xx responses. It now returns an error if the total size of all 1xx responses exceeds 10MB.

- Bump bpm to version [1.4.17](#)
- Bump cf-networking to version [3.69.0](#)
- Bump cflinuxfs3 to version [0.623.0](#)
- Bump cflinuxfs4 to version [1.296.0](#)
- Bump cf-cli to version [2.0.0](#)
- Bump loggregator-agent to version [8.3.7](#)
- Bump nfs-volume to version [7.25.0](#)
- Bump otel-collector to version [0.11.4](#)
- Bump routing to version [0.334.0](#)
- Bump silk to version [3.69.0](#)
- Bump smb-volume to version [3.24.0](#)
- Bump syslog to version [12.3.9](#)

## Security Fixes

The following table lists CVEs that were fixed in each Isolation Segment component since the previous patch version of Isolation Segment:

## 6.0.8

**Release Date:** 09/27/2024

- **[Bug Fix]** Fixes a bug preventing TCP Routing from working on IST/TASW tiles when the TAS Routing API Endpoint Protocol is configured to be HTTPS only
- Bump bpm to version [1.3.2](#)
- Bump cf-networking to version [3.50.0](#)

- Bump cflinuxfs3 to version 0.407.0
- Bump cf-cli to version 1.67.0
- Bump diego to version 2.103.0
- Bump garden-runc to version 1.56.0
- Bump loggregator-agent to version 8.2.1
- Bump mapfs to version 1.3.0
- Bump nfs-volume to version 7.2.0
- Bump otel-collector to version 0.10.1
- Bump routing to version 0.311.0
- Bump silk to version 3.50.0
- Bump smb-volume to version 3.4.0
- Bump syslog to version 12.3.3

## 6.0.7

Release Date: 08/22/2024

### Caution

If you are upgrading from v6.0.5 or v6.0.6 to a later patch version, upgrade TAS for VMs and apply those changes before you upgrade Isolation Segment. Failure to upgrade TAS for VMs first will result in TCP route outages on Isolation Segment.

For more information, see [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#) in the Broadcom Support Knowledge Base.

- **[Bug Fix]** Fixes known issue [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#)
- Bump bpm to version [1.3.0](#)
- Bump cflinuxfs3 to version [0.391.0](#)
- Bump diego to version [2.102.0](#)
- Bump garden-runc to version [1.54.0](#)
- Bump loggregator-agent to version [8.1.5](#)
- Bump otel-collector to version [0.7.0](#)
- Bump routing to version [0.304.0](#)
- Bump syslog to version [12.3.1](#)

#### ▼ v0.302.0

```

## 0.302.0
**Release Date**: August 08, 2024
## Changes
- Adds drain_wait + load_balancer_healthy_
threshold properties behaving similarly to go
router's to provide better uptime during BOSH
deployments by waiting for LBs to pull nodes
about to be shut down out of service, and re-
add them before moving on to the next.
- Adds support for TLS backends with TCP r
outes. This enables TCP routes to use the env
oy proxy settings on app containers used by H
TTP routes, providing guaranteed TLS encrypti
on between tcp-router + diego-cell VMs, witho
ut intervention from app teams. Additionally
it allows for the disabling of the unproxied
ports on containers since TCP route traffic c
an now go through envoy.
- Fixed a bug with v0.301.0 that caused pr
oblems with TCP routes when a postgres databa
se was used for the routing-api. Thanks for
[finding this] (https://github.com/cloudfoundr
y/routing-api/issues/57) @schmidtsv!
- Bumped to golang 1.22.5
- Bumped tcp_router's haproxy to 2.8.10
- Testing + docs improvements
## Bosh Job Spec changes:

## 6.0.6

**Release Date:** 07/29/2024

### Caution

This release is affected by a known issue for customers who use both Postgres for the TAS for VMs database and TCP Routes. Users who use both Postgres and TCP Routes should not upgrade to this version. This only applies if Postgres is used for the core Cloud Foundry databases, not if apps use Postgres services.

### Caution

If you are upgrading from v6.0.5 or v6.0.6 to a later patch version, upgrade TAS for VMs and apply those changes before you upgrade Isolation Segment. Failure to upgrade TAS for VMs first will result in TCP route outages on Isolation Segment.

For more information, see [Downtime for TCP Routes When Upgrading IST, TASW, and Services Tiles before TAS in TPCF](#) in the Broadcom Support Knowledge Base.

- **[Bug Fix]** Resolves a rare issue leading to pre-start script failures in the garden-cni + vxlan-policy-agent jobs on diego-cells
- **[Bug Fix]** Adds 2 minute caching for failed dns lookups in syslog agent to avoid dns load for malformed drain urls.
- **[Feature]** Adds `PrometheusRemoteWrite` exporter and `batch` processor.
- Bump bpm to version [1.2.23](#)
- Bump cf-networking to version [3.47.0](#)
- Bump cflinuxfs4 to version [1.107.0](#)
- Bump cf-cli to version [1.65.0](#)
- Bump loggregator-agent to version [8.1.3](#)
- Bump nfs-volume to version [7.1.75](#)
- Bump otel-collector to version [0.6.0](#)

- Bump silk to version 3.47.0
- Bump smb-volume to version 3.1.74

tanzu-jammy-stack	1.0.1	

## 6.0.0

Release Date: 04/09/2024

This release is susceptible to a [known issue](#) where Gorouter returns an incorrect HTTP status code in response to requests with an "HTTP 100 Continue" interim status header. To resolve this issue, see the Broadcom Knowledge Base article [Gorouter Returns wrong HTTP response code to client when the request flow uses HTTP 100-continue](#).

- **[Breaking Change]** Change default internal route service port to 7070
- **[Breaking Change]** Replace cpu entitlement counters with cpu\_entitlement percentage gauge
- **[Breaking Change]** Remove (deprecated) Metrics Agent and Metrics Discovery Release
- **[Breaking Change]** Gorouter's deprecated /varz and /healthz endpoints on port 8080 have been removed
- **[Feature]** Add support for NTLM authentication in Gorouter
- **[Feature]** Adds Diego support for Docker workloads using OCI images
- **[Feature]:** Gorouters can be configured to prefer routing to app instances in the same AZ as the router
- **[Feature]** Operators can now turn off non-TLS load balancer health check endpoints for Gorouter and TCP Router via the “Enable HTTP load balancer health checks” properties in the “Networking” tab
- **[Feature]** Gorouter now supports LB Health Checks over TLS on port 8443
- **[Feature]** Expose a custom environment identifier on component logs forwarded via syslog
- **[Feature Improvement]** Make database “encrypt key” setting more intentional, to avoid password-manager autofilling of the field
- **[Feature Improvement]** Reintroduce global log rate limit
- **[Feature Improvement]** Apps using readiness health checks will now see audit.app.process.notready and audit.app.process.ready events reported to `cf events`

- **[Feature Improvement]** Garden now emits an `UnkillableContainers` metric to help identify cells that will be unable to redeploy successfully without operator intervention
- **[Feature Improvement]** Adds opt-in support for NTLM + other challenge-response based authentication using `Authorization: Negotiate` flows by automatically enabling sticky sessions for those requests.
- **[Feature Improvement]** Adds support for `Partitioned` cookies to allow for sticky sessions in embedded contexts.
- **[Feature Improvement]** OTel Collector marks OTLP Sums as monotonic if they originate from a Loggregator counter
- **[Feature Improvement]** Allow to configure w3c tracing headers in router

## How to install

To install Isolation Segment v6.0, see [Installing Isolation Segment](#).

To install Isolation Segment v6.0, you must first install Tanzu Operations Manager v6.0. For more information, see the [VMware Tanzu Operations Manager documentation](#).

## New features in Isolation Segment v6.0

These are the new features for Isolation Segment v6.0.

### Reintroduction of global log rate limit

TAS v3.0 introduced granular app log rate limits for fine-grained control over application log rates.

Isolation Segment v4.0 removed the older global log rate limit feature **App log rate limit (deprecated)** under **App Containers**. This was problematic for operators who were performing a jump upgrade to Isolation Segment v4.0 (skipping v3.0), as logs would not be rate limited until application-based log rate limits were applied.

Isolation Segment v6.0 restores the global log rate limit, so that operators can perform upgrades while retaining log rate limits. Operators must configure the same setting separately for both VMware Tanzu Application Service for VMs and TAS for VMs [Windows].

If you had previously set a global log rate limit, this limit is re-applied following the upgrade to Isolation Segment v6.0.

## Breaking changes

There are no breaking changes for Isolation Segment v6.0.

## Known issues

There are no known issues for Isolation Segment v6.0.

# Architecture

In this section:

- **Components**
  - TAS for VMs components

## Components

In this section:

- TAS for VMs runtime components
- Diego components and architecture
- TAS for VMs routing architecture
- Cloud Controller

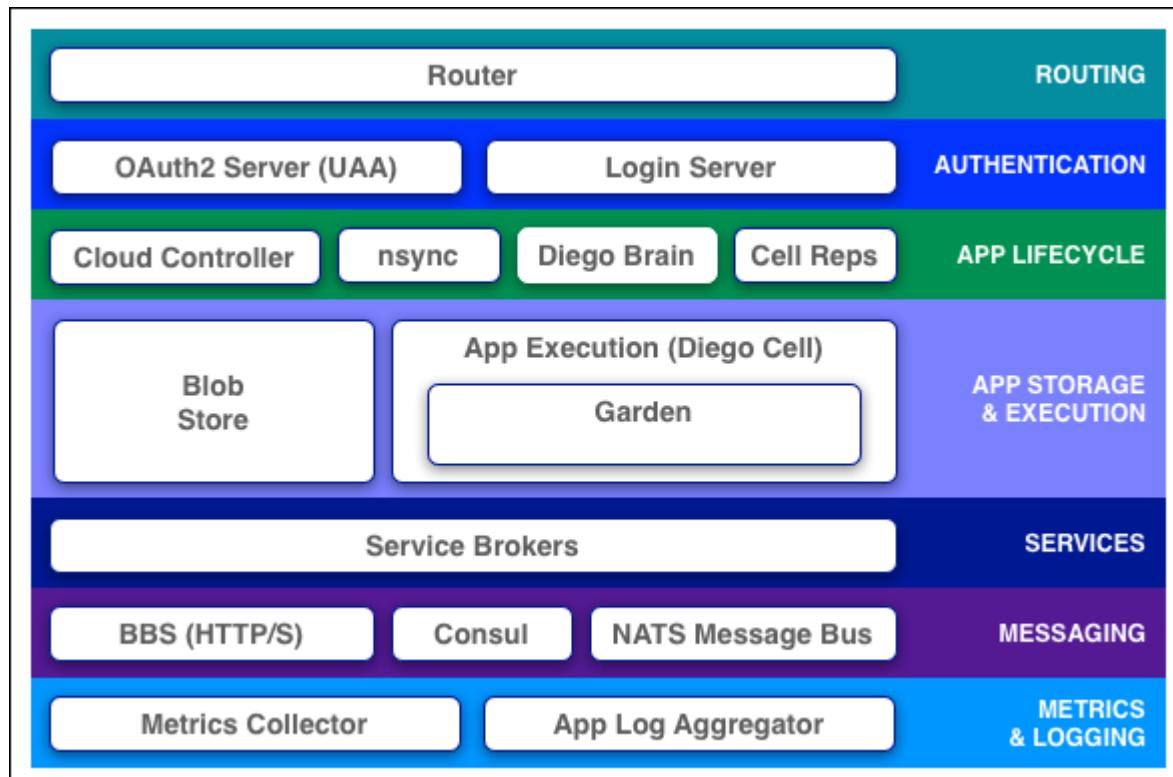

- Cloud Controller blobstore
- Garden components
- GrootFS disk usage
- HTTP routing
- User Accounts and Authentication overview
- Services
- CredHub

## TAS for VMs runtime components

This topic tells you about the VMware Tanzu Application Service for VMs (TAS for VMs) runtime components.

TAS for VMs components include a self-service application execution engine, an automation engine for application deployment, and lifecycle management, and a scriptable command line interface (CLI). Also, an integration with development tools to ease deployment processes. TAS for VMs has an open architecture that includes a buildpack mechanism for adding frameworks, an application services interface, and a cloud provider interface.

See the following descriptions for more information about TAS for VMs components. Some descriptions include links to more detailed documentation.

## Routing

### Router

The router routes incoming traffic to the appropriate component, either a Cloud Controller component or a hosted application running on a Diego Cell.

The router periodically queries the Diego Bulletin Board System (BBS) to determine which cells and containers each application currently runs on. Using this information, the router recomputes new routing tables based on the IP address of each cell virtual machine (VM) and the host-side port numbers for the cell's containers.

For more information about the routing tier, including the router, see [TAS for VMs Routing Architecture](#).

## Authentication

### OAuth2 Server (UAA) and Login Server

The OAuth2 server (the [UAA](#)) and Login Server work together to provide identity management.

## App Lifecycle

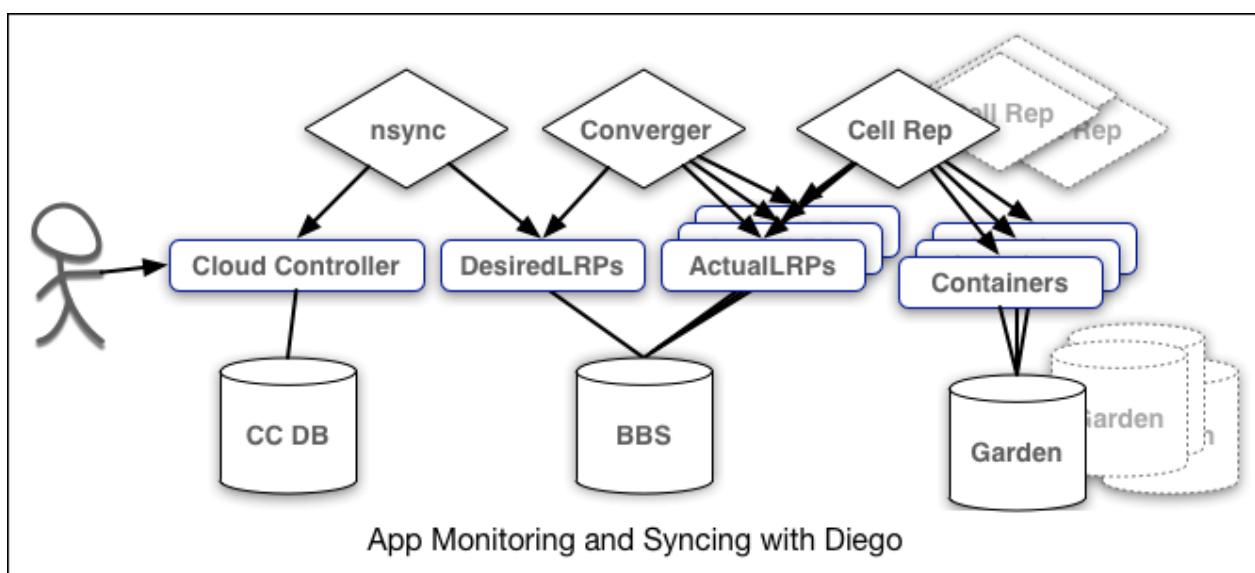

### Cloud Controller and Diego Brain

The [Cloud Controller](#) (CC) directs the deployment of applications. To push an app to TAS for VMs, you target the Cloud Controller. The Cloud Controller then directs the Diego Brain through the CC-Bridge components to coordinate individual [Diego cells](#) to stage and run applications.

The Cloud Controller also maintains records of [orgs](#), [spaces](#), [user roles](#), services, and more.

### nsync, BBS, and Cell Reps

To keep applications available, cloud deployments must constantly monitor their states and reconcile them with their expected states, starting and stopping processes as required.

The nsync, BBS, and Cell Rep components work together along a chain to keep apps running. At one end is the user. At the other end are the instances of applications running on widely-distributed VMs, which might crash or become unavailable.

Here is how the components work together:

- **nsync** receives a message from the Cloud Controller when the user scales an app. It writes the number of instances into a `DesiredLRP` structure in the Diego BBS database.
- **BBS** uses its convergence process to monitor the `DesiredLRP` and `ActualLRP` values. It runs or stops application instances as appropriate to ensure the `ActualLRP` count matches the `DesiredLRP` count.
- **Cell Rep** monitors the containers and provides the `ActualLRP` value.

## App Storage and Execution

### Blobstore

The blobstore is a repository for large binary files, which GitHub cannot easily manage because GitHub is designed for code. The blobstore contains the following:

- Application code packages
- Buildpacks
- Droplets

You can configure the blobstore as either an internal server or an external S3 or S3-compatible endpoint. For more information about the blobstore, see [How to use Elastic Runtime BLOB Storage Data] (<https://broadcomcms-software.wolkenservicedesk.com/external/article?articleNumber=297819>)

### Diego Cell

Application instances, application tasks, and staging tasks all run as `Garden` containers on the Diego Cell VMs. The Diego cell rep component manages the lifecycle of those containers and the processes running in them, reports their status to the Diego BBS, and emits their logs and metrics to `Loggregator`.

## Services

### Service Brokers

Applications typically depend on `services` such as databases or third-party SaaS providers. When a developer provisions and binds a service to an application, the service broker for that service is responsible for providing the service instance.

### Messaging

### Internal HTTPS and BBS

The component VMs of TAS for VMs communicate with each other internally through HTTP and HTTPS protocols, sharing temporary messages and data stored in Diego's `Bulletin Board System (BBS)`.

- BOSH Director collocates a `BOSH DNS` server on every deployed VM. All VMs keep up-to-date DNS records for all the other VMs in the same foundation, enabling service discovery between VMs. BOSH DNS also provides client-side load-balancing by randomly selecting a healthy VM when multiple VMs are available.

- Diego's [Bulletin Board System](#) (BBS) stores more frequently updated and disposable data such as cell and app status, unallocated work, and heartbeat messages, as well as longer-lived distributed locks. The BBS stores data in MySQL, using the [Go MySQL Driver](#).

The route emitter component uses the NATS protocol to broadcast the latest routing tables to the routers.

## Metrics and Logging

### Loggregator

The Loggregator (log aggregator) system streams application logs to developers.

For more information about the Loggregator architecture, see [Loggregator Architecture](#).

## Diego components and architecture

This topic tells you about the components that form and interact with the Diego system in VMware Tanzu Application Service for VMs (TAS for VMs).

TAS for VMs uses the Diego system to manage app containers. Diego components assume app scheduling and management responsibility from the Cloud Controller.

Diego is a self-healing container management system that attempts to keep the correct number of instances running in Diego cells to avoid network failures and crashes. Diego schedules and runs Tasks and Long-Running Processes (LRP). For more information about Tasks and LRPs, see [How the Diego Auction Allocates Jobs](#).

You can submit, update, and retrieve the desired number of Tasks and LRPs using the Bulletin Board System (BBS) API. For more information, see the [BBS Server](#) repository on GitHub.

## Learning how Diego runs an app

The following sections describe how Diego handles a request to run an app. This is only one of the processes that happen in Diego. For example, running an app assumes the app has already been staged.

For more information about the staging process, see [How Apps are Staged](#).

The following illustrations and descriptions do not include all of the components of Diego. For information about each Diego component, see [Diego Components](#).

The architecture discussed in the following steps includes the following high level blocks:

- api - cloud\_controller\_ng
- scheduler - auctioneer
- diego-api - bbs
- pxc-mysql - bbs db
- diego-cell - rep/executor, garden, loggregator-agent, route-emitter
- singleton-blobstore - droplets
- doppler - doppler
- log-api - traffic-controller

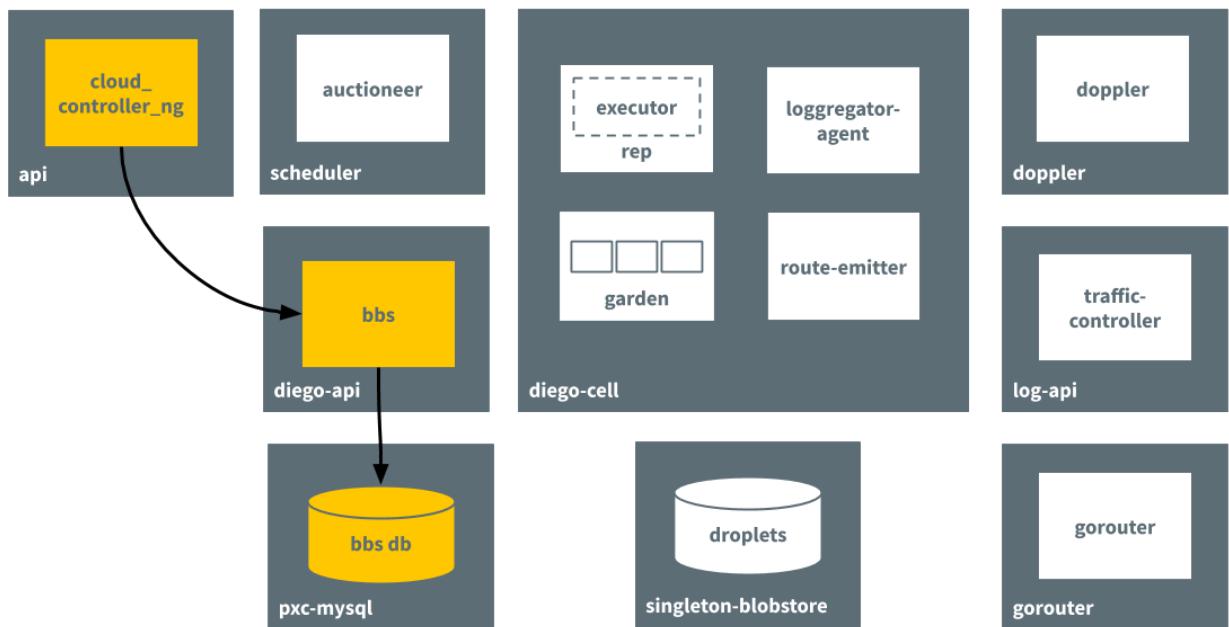

- gorouter - gorouter

The images below are based on the VM names in an open-source deployment of Cloud Foundry Application Runtime. In TAS for VMs, the processes interact in the same way, but are on different VMs. Correct VM names for each process are in the components sections of this topic.

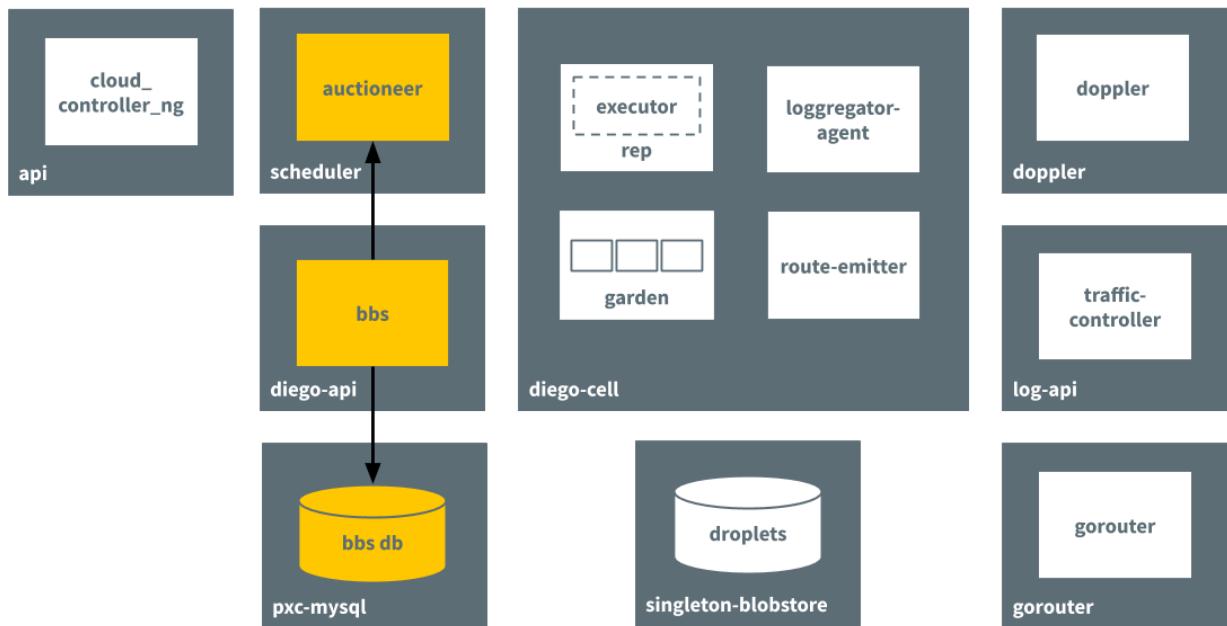

## Step 1: Receiving the request to run an app

Cloud Controller passes requests to run apps to the Diego BBS, which stores information about the request in its database.

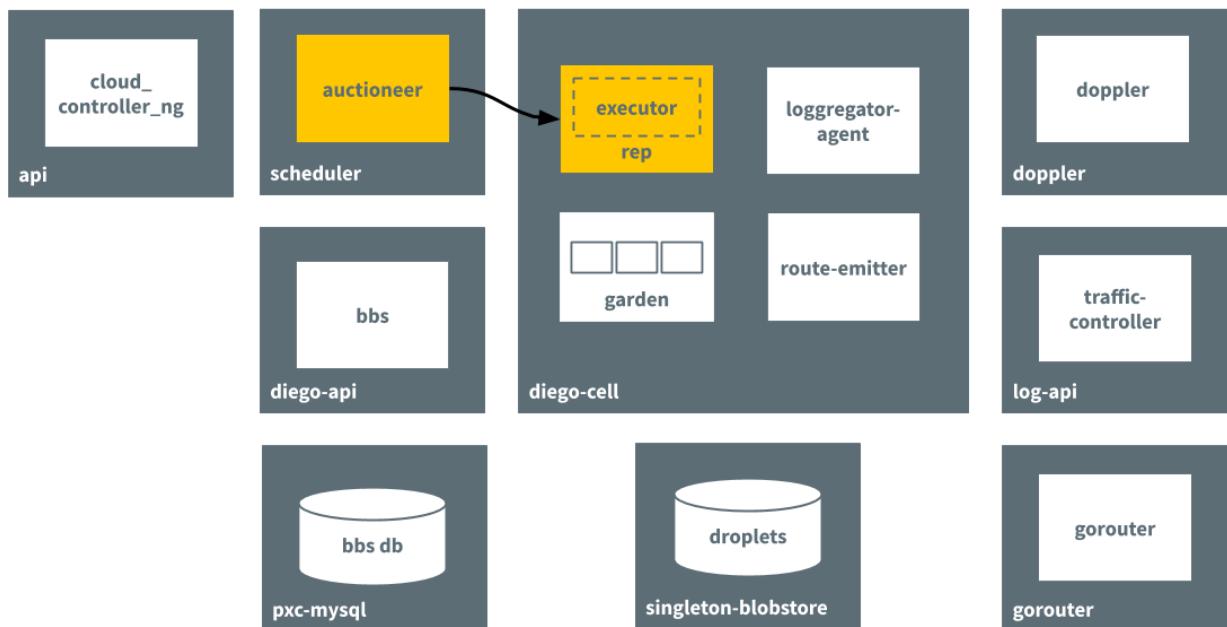

## Step 2: Passing the request to the auctioneer process

The BBS contacts the Auctioneer to create an auction based on the desired resources for the app. It references the information stored in its database.

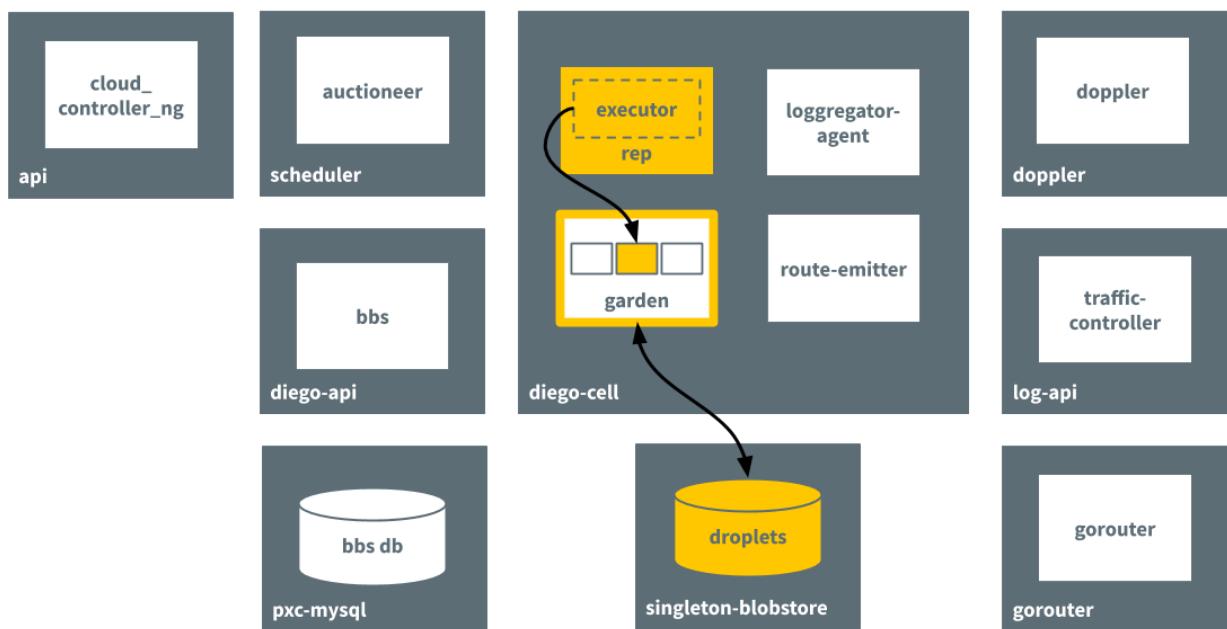

### Step 3: Performing the auction

Through an auction, the Auctioneer finds a Diego Cell to run the app on. The Rep job on the Diego Cell accepts the auction request.

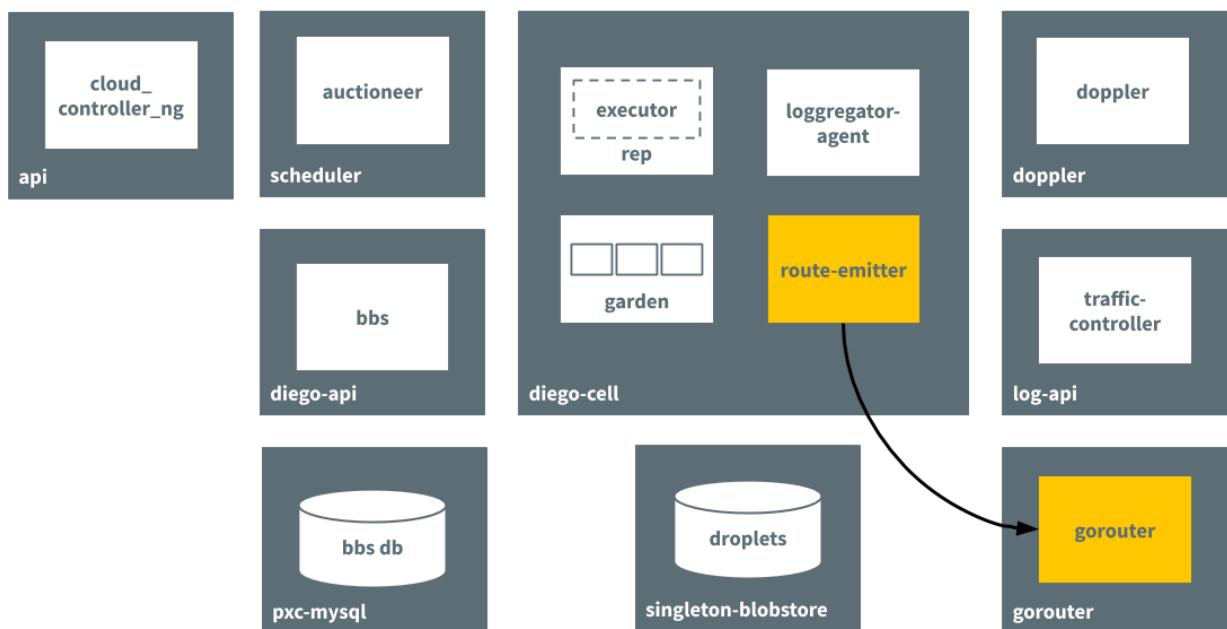

### Step 4: Creating the container and running the app

The in process Executor creates a Garden container in the Diego Cell. Garden downloads the droplet that resulted from the staging process and runs the app in the container.

## Step 5: Emitting a route for the app

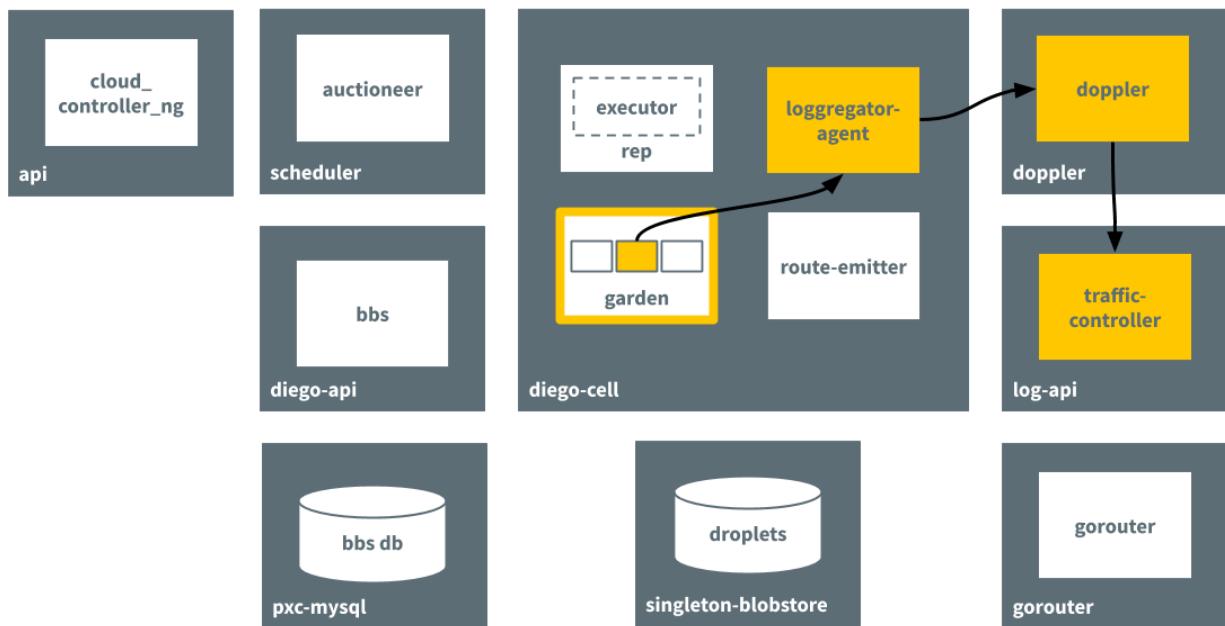

The `route-emitter` process emits a route registration message to Gorouter for the new app running on the Diego Cell.

## Step 6: Sending logs to the Loggregator

Loggregator agent forwards app logs, errors, and metrics to the TAS for VMs Loggregator.

For more information, see [App Logging in TAS for VMs](#).

## Diego components

The following table describes the jobs that are part of the TAS for VMs Diego BOSH release.

Component	Function
<b>Job:</b> auctioneer	<ul style="list-style-type: none"> <li>Distributes work through auction to Cell Reps over SSL/TLS. For more information, see <a href="#">How the Diego Auction Allocates Jobs</a>.</li> </ul>
<b>VM:</b> diego_brain	<ul style="list-style-type: none"> <li>Maintains a lock in Locket to ensure only one auctioneer handles auctions at a time.</li> </ul>
<b>Job:</b> bbs	<ul style="list-style-type: none"> <li>Maintains a real-time representation of the state of the Diego cluster, including desired LRPs, running LRPs, and in-flight Tasks.</li> </ul>
<b>VM:</b> diego_database	<ul style="list-style-type: none"> <li>Provides an RPC-style API over HTTP to Diego Core components for external clients as well as internal clients, including the SSH Proxy and Route Emitter.</li> <li>Ensures consistency and fault tolerance for Tasks and LRPs by comparing desired state with actual state.</li> <li>Keeps <code>DesiredLRP</code> and <code>ActualLRP</code> counts synchronized. If the <code>DesiredLRP</code> count exceeds the <code>ActualLRP</code> count, requests a start auction from the Auctioneer. If the <code>ActualLRP</code> count exceeds the <code>DesiredLRP</code> count, sends a stop message to the Rep on the Diego Cell hosting an instance.</li> </ul>
<b>Job:</b> file_server	<ul style="list-style-type: none"> <li>Serves static assets that can include general-purpose App Lifecycle binaries</li> </ul>
<b>VM:</b> diego_brain	
<b>Job:</b> locket	<ul style="list-style-type: none"> <li>Provides a consistent key-value store for maintenance of distributed locks and component presence</li> </ul>
<b>VM:</b> diego_database	

Component	Function
<b>Job:</b> rep	<ul style="list-style-type: none"> <li>Represents a Diego Cell in Diego Auctions for Tasks and LRPCs</li> </ul>
<b>VM:</b> diego_cell	<ul style="list-style-type: none"> <li>Runs Tasks and LRPCs by creating a container and then running actions in it</li> <li>Periodically ensures its set of Tasks and ActualLRPs in the BBS is in sync with the containers actually present on the Diego Cell</li> <li>Manages container allocations against resource constraints on the Diego Cell, such as memory and disk space</li> <li>Streams stdout and stderr from container processes to the metron-agent running on the Diego Cell, which in turn forwards to the Loggregator system</li> <li>Periodically collects container metrics and emits them to Loggregator</li> <li>Mediates all communication between the Diego Cell and the BBS</li> <li>Maintains a presence record for the Diego Cell in Locket</li> </ul>
<b>Job:</b> route_emitter	<ul style="list-style-type: none"> <li>Monitors <code>DesiredLRP</code> and <code>ActualLRP</code> states, emitting route registration and unregistration messages to Gorouter when it detects changes.</li> </ul>
<b>VM:</b> diego_cell	<ul style="list-style-type: none"> <li>Periodically emits the entire routing table to the TAS for VMs Gorouter.</li> </ul>
<b>Job:</b> diego-healthchecker	<ul style="list-style-type: none"> <li>An executable designed to perform TCP/HTTP based health checks of processes managed by monit in BOSH releases.</li> </ul>
<b>VM:</b> diego_cell	<ul style="list-style-type: none"> <li>Because the version of monit included in BOSH does not support specific tcp/http health checks, we designed this utility to perform health checking and restart processes if they become unreachable.</li> </ul>
<b>Job:</b> ssh_proxy	<ul style="list-style-type: none"> <li>Brokers connections between SSH clients and SSH servers</li> </ul>
<b>VM:</b> diego_brain	<ul style="list-style-type: none"> <li>Runs inside instance containers and authorizes access to app instances based on Cloud Controller roles</li> </ul>

## Additional information

The following resources provide more information about Diego components:

- The [Diego Release](#) repository on GitHub.
- The [Auctioneer](#) repository on GitHub.

- The [File Server](#) repository on GitHub.
- The [Rep](#) repository on GitHub.
- The [Executor](#) repository on GitHub.
- The [Route-Emitter](#) repository on GitHub.
- [App SSH](#), [App SSH Overview](#), and the [Diego SSH](#) repository on GitHub.

## Maximum recommended Diego Cells

The maximum recommended Diego Cells is 250 Cells for each TAS for VMs deployment. By default, there is a hard limit of 256 addresses for vSphere deployments that use Silk for networking. This hard limit is

described in the [Silk Release documentation](#) on GitHub.

The default CIDR address block for the overlay network is 10.255.0.0/16. Each Diego Cell requires a subnet, and subnets (0-255) for each Diego Cell are allocated out of this network.

TAS for VMs deployments that do not use Silk for networking do not have a hard limit. However, operating a foundation with more than 250 Diego Cells is not recommended for the following reasons:

- Changes to the foundation can take a long time, potentially days or weeks depending on the `max-in-flight` value. For example, if there is a certificate expiring in a week, there might not be enough time to rotate the certificates before expiry. For more information, see [Basic Advice](#) in [Configuring TAS for VMs for Upgrades](#).
- A single foundation still has single points of failure, such as the certificates on the platform. The RAM that 250 Diego Cells provides is enough to host many business-critical apps.

## Components from other releases

The following table describes jobs that interact closely with Diego but are not part of the Diego TAS for VMs BOSH release.

Component	Function
<b>Job:</b> bosh-dns-aliases	<ul style="list-style-type: none"> <li>Provides service discovery through colocated DNS servers on all BOSH-deployed VMs</li> </ul>
<b>VM:</b> all	<ul style="list-style-type: none"> <li>Provides client-side load-balancing by randomly selecting a healthy VM when multiple VMs are available</li> </ul>
<b>Job:</b> cc_uploader	<ul style="list-style-type: none"> <li>Mediates uploads from the Executor to the Cloud Controller</li> </ul>
<b>VM:</b> diego_brain	<ul style="list-style-type: none"> <li>Translates simple HTTP POST requests from the Executor into complex multipart-form uploads for the Cloud Controller</li> </ul>
<b>Job:</b> database	<ul style="list-style-type: none"> <li>Provides a consistent key-value data store to Diego</li> </ul>
<b>VM:</b> mysql	
<b>Job:</b> loggregator-agent	<ul style="list-style-type: none"> <li>Forwards app logs, errors, and app and Diego metrics to the Loggregator Doppler component</li> </ul>
<b>VM:</b> all	
<b>Job:</b> cloud_controller_clo	<ul style="list-style-type: none"> <li>Runs a Diego sync process to ensure desired app data in Diego is in sync with the Cloud Controller.</li> </ul>
<b>VM:</b> clock_global	

## App lifecycle binaries

The following platform-specific binaries deploy apps and govern their lifecycle:

- The **Builder**, which stages a TAS for VMs app. The Builder runs as a Task on every staging request. It performs static analysis on the app code and does any necessary pre-processing before the app is first run.

- The **Launcher**, which runs a TAS for VMs app. The Launcher is set as the Action on the `DesiredLRP` for the app. It runs the start command with the correct system context, including working directory and environment variables.
- The **Healthcheck**, which performs a status check on running TAS for VMs app from inside the container. The Healthcheck is set as the CheckDefinition on the `DesiredLRP` for the app.

## Current implementations

- The buildpack app lifecycle implements the TAS for VMs buildpack-based deployment strategy. For more information, see the [buildpackapplifecycle](#) repository on GitHub.
- The Docker app lifecycle implements a Docker deployment strategy. For more information, see the [dockerapplifecycle](#) repository on GitHub.

## Additional information

The following resources provide more information about components from other releases that interact closely with Diego:

- The [CC-Uploader](#) repository on GitHub.
- [Garden](#) or the [Garden](#) repository on GitHub.
- The [Loggregator Release](#) repository on GitHub.
- The [BOSH DNS documentation](#).
- The [TPS](#) repository on GitHub.

## TAS for VMs Routing Architecture

This topic tells you about the routing architecture and flow in VMware Tanzu Application Service for VMs (TAS for VMs).

## Routing architecture components

The following summarizes the roles and responsibilities of various components depicted in the TAS for VMs routing architecture diagrams. These summaries are limited to the roles and responsibilities these components have pertaining to routing. For more complete descriptions of these components, see [TAS for VMs Concepts](#), [TAS for VMs Components](#), and [Diego Components and Architecture](#).

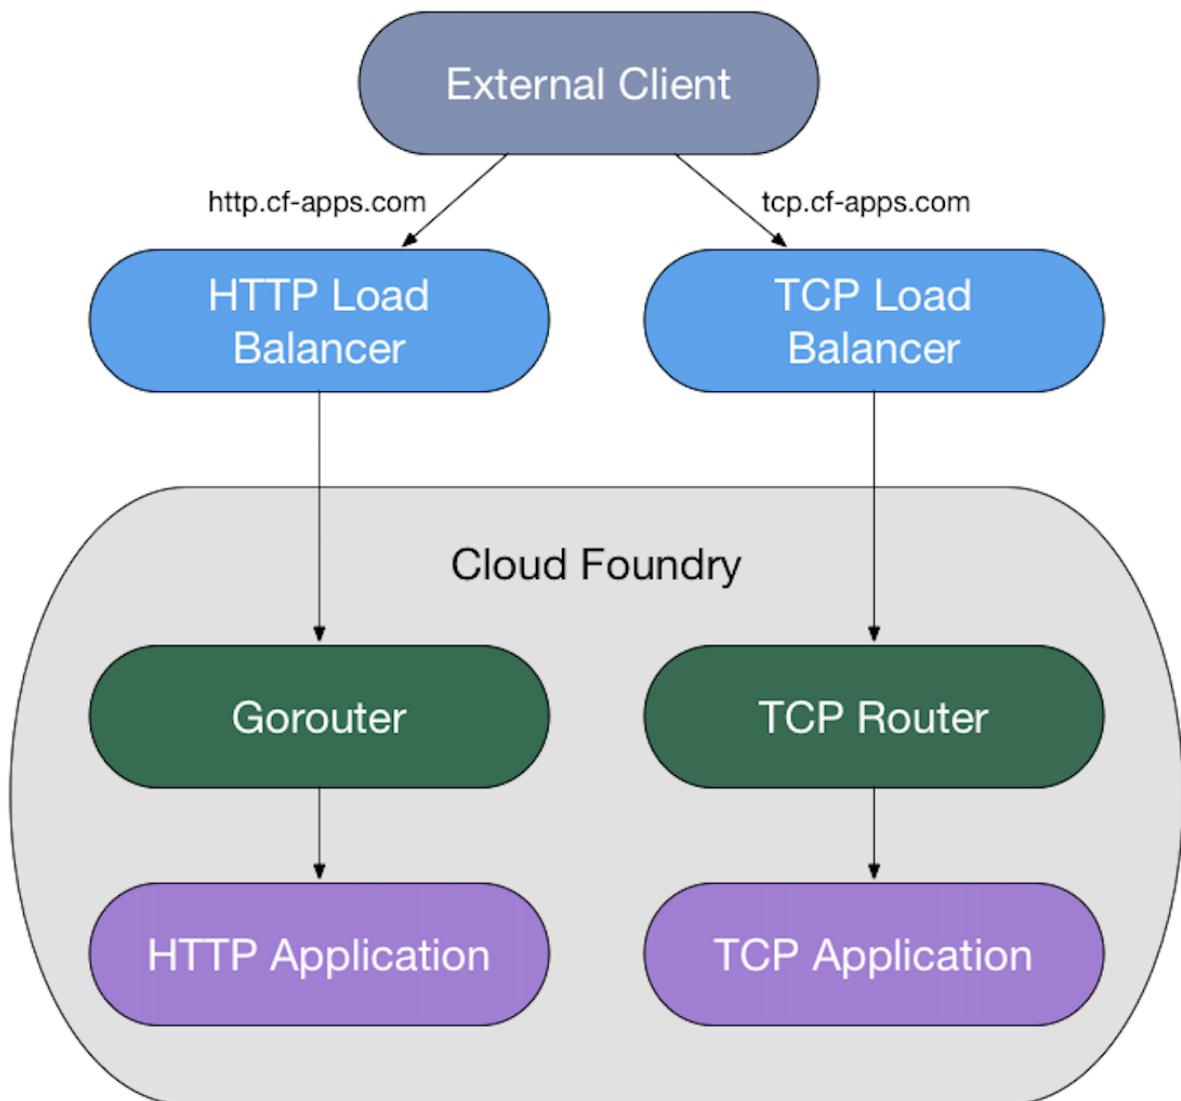

Component Name	Summary
BOSH manifest	Used to configure route registrar with route(s) for system components such as UAA and Loggregator.
Cloud Controller	Contains route metadata, including whether they are HTTP or TCP.
Diego BBS	Contains IP and port metadata as well as route metadata from Cloud Controller, which route emitter discovers.

<b>Component Name</b>	<b>Summary</b>
Diego cell	Manages app instances and tasks and long-running processes related to them. A route emitter runs on each cell.
Gorouter	Routes HTTP traffic coming into TAS for VMs to the appropriate component. Receives route updates through NATS. Routes that have not been updated in two minutes are pruned from the Gorouter's database.
NATS	Receives routing configuration from route emitter and provides same to Gorouter.
Route registrar	Sends routing metadata described in BOSH manifest for system components such as UAA and Loggregator to NATS. This is because the Diego cell does not have information about system components, only about user spaces.
Route emitter	Periodically emits route, IP, and port metadata to NATS or Routing API as registration and unregistration messages. Does not know about app instances on Diego cell, but knows what cell it belongs to and learns about what app instances are running on its cell by asking Diego BBS for information about app instances on the same cell.
Routing API	Receives routing configuration from route emitter and other internal clients, and provides routing configuration for TCP router.
Routing database	Saves some routing data from Routing API. If the Gorouter misses a message about an unmapped route from NATS, it does not get it again, so TCP router and Routing API can consult routing database for current state of routes.
TCP router	Routes TCP traffic coming into TAS for VMs to the appropriate component. Receives route updates through the routing API.
HealthChecker	An executable designed to perform TCP/HTTP-based health checks of processes managed by monit in BOSH releases. Because the version of monit included in BOSH does not support specific TCP/HTTP health checks, this utility is designed to perform health checking, and restart processes if they become unreachable.

## Making a request to external client

The following process tells you about how an external client makes a request to an app running on TAS for VMs:

1. The external client sends its request.
2. Your DNS service sends the request to the HTTP or TCP load balancer based on the prefix of the DNS name in the client request, such as `http` in `http.example.com`.
3. The load balancer sends the request to the load balancer's corresponding router.
4. The router sends the request to the app.

## Maintaining updated routing tables

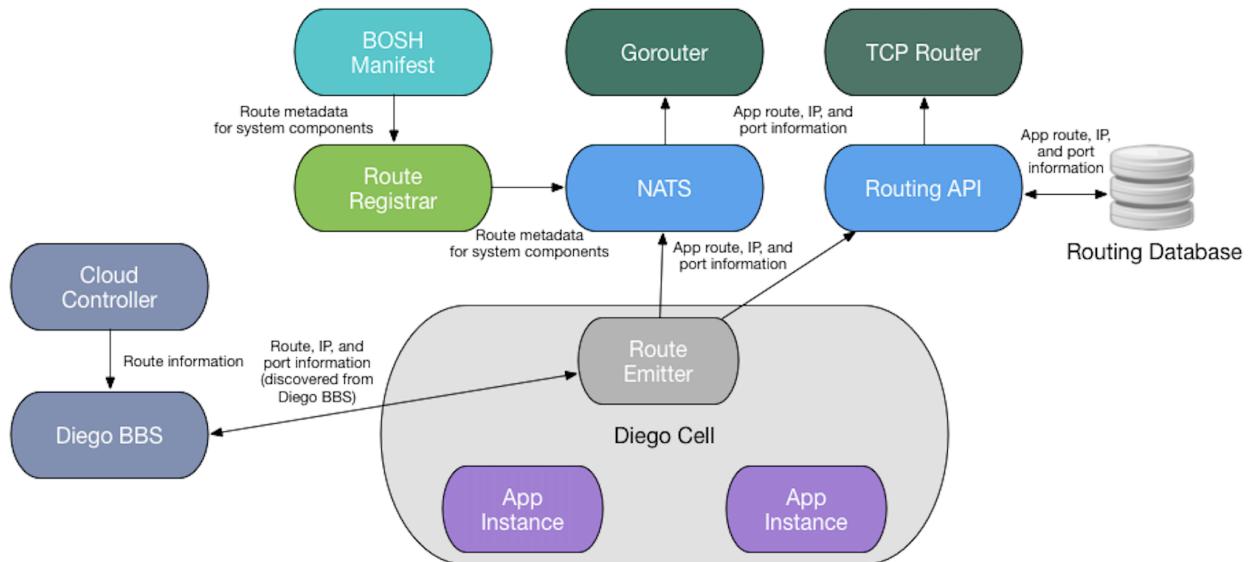

Because each app can have many instances, one app route can go to multiple containers. As Diego moves and scales app instances, the route emitter on each cell sends messages to NATS or the Routing API to register and deregister routes to the cell's app instances.

The route emitter periodically emits the routes it discovers from Diego BBS to NATS and the Routing API as registration and unregistration messages every twenty seconds. The Gorouter uses TLS to verify app identity and confirm that its routes are up-to-date. For more information about how TAS for VMs maintains route consistency, see [Preventing Misrouting in HTTP Routing](#).

The following process describes how a router obtains information about routes for an app running on TAS for VMs:

1. Cloud Controller component sends app route information to Diego BBS. For HTTP routing, route information includes the host and path of an external URL, as shown in the format of the `router.register` message in the Gorouter documentation on GitHub. For TCP routing, route information includes the route port on which the TCP connection was received; for more information, see the [Routing API documentation on GitHub](#).

2. Diego BBS coordinates the back end IP address and port where each instance of the app runs. When queried by the route emitter, the BBS sends this information along with the Cloud Controller app route information to the route emitter on the Diego cell where instances of the app are located.
3. If a route is HTTP, the route emitter on the Diego cells sends app route, IP, and port information to NATS, which then sends it to the Gorouter. If a route is TCP, the route emitter sends that information to the Routing API, which then sends it to the TCP router.
4. Gorouter and TCP router use the route, IP, and port information from the route emitter to map incoming app requests to back end app instance locations.

## Routing table recovery after component failure

Cloud Controller and Diego BBS have their own databases, while NATS and the Gorouter only store their data in memory. If NATS or the Gorouter are restarted, they lose all of their data and must wait for the route emitter to send data to them again. If Diego BBS is restarted, it can retrieve its data from Cloud Controller. If Cloud Controller is restarted, you must retrieve its data from a backup.

## Cloud Controller

Cloud Controller in VMware Tanzu Application Service for VMs (TAS for VMs) provides you with REST API endpoints to access the system. Cloud Controller maintains a database with tables for orgs, spaces, services, user roles, and more.

## Diego Auction

The Cloud Controller uses the [Diego Auction](#) to balance application processes over the [Diego Cells](#) in a TAS for VMs installation.

## Database (CC\_DB)

The Cloud Controller database has been tested with MySQL.

## Blobstore

To stage and run apps, TAS for VMs manages and stores app source code and other files in an S3-compatible blobstore.

Please see [Cloud Controller blobstore](#) for information.

## Testing

By default `rspec` runs a test suite with the SQLite in-memory database. Specify a connection string using the `DB_CONNECTION` environment variable to test against MySQL. For example:

```
DB_CONNECTION="mysql2://root:password@localhost:3306/ccng" rspec
```

## Cloud Controller blobstore

To stage and run apps, TAS for VMs manages and stores the following types of binary large object (blob) files:

Blob Type	Description	Location in Blobstore
App Package	Full contents of app directories, including source code and resource files, zipped into single blob files.	/cc-packages
Buildpacks	Buildpack directories, which Diego cells download to compile and stage apps with.	/cc-buildpacks
Resource Cache	Large files from app packages that the Cloud Controller stores with a SHA for later re-use. To save bandwidth, the TAS for VMs Command Line Interface (cf CLI) only uploads large application files that the Cloud Controller has not already stored in the resource cache.	/cc-resources
Buildpack Cache	Large files that buildpacks generate during staging, stored for later re-use. This cache lets buildpacks run more quickly when staging apps that have been staged previously.	cc-droplets/buildpack_cache
Droplets	Staged apps packaged with everything needed to run in a container.	/cc-droplets

TAS for VMs blobstores use the [Fog](#) Ruby gem to store blobs in services like Amazon S3, WebDAV, or the NFS filesystem. The file system location of an internal blobstore is `/var/vcap/store/shared`.

A single blobstore typically stores all five types of blobs, but you can configure the Cloud Controller to use separate blobstores for each type. This topic references staging and treats all blobstores as generic object stores.

For more information about staging, see [How Apps Are Staged](#).

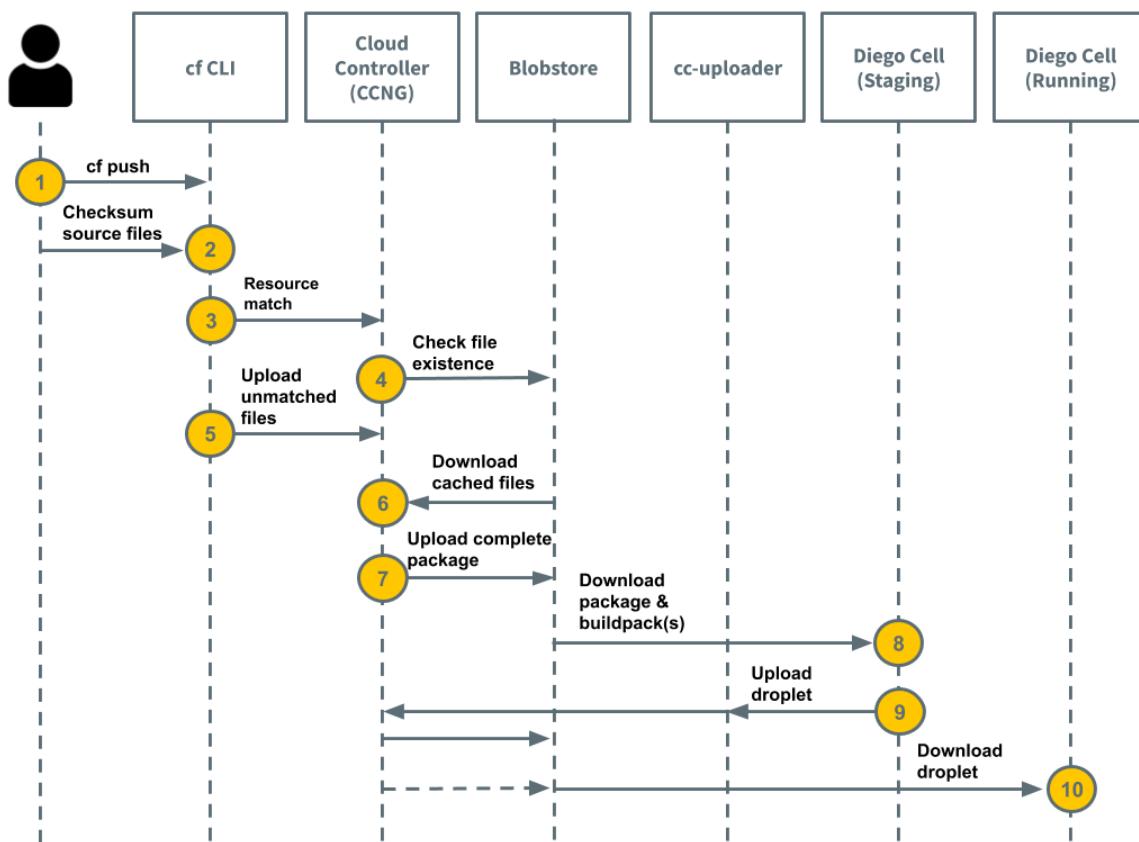

For more information about how specific third-party blobstores can be configured, see [Configuring File Storage for TAS for VMs](#).

## Staging using the blobstore

This section describes how staging buildpack apps uses the blobstore.

The following diagram illustrates how the staging process uses the blobstore. To walk through the same diagram in an app staging context, see [How Diego Stages Buildpack Apps](#). The staging process for buildpack apps includes a developer and the following components: CF Command Line, Cloud Controller (CCNG), Blobstore, cc-uploader, Diego Cell (Staging), and Diego Cell (Running).

- Step 1: cf push from Developer to CF CLI.
- Step 2: Checksum source files from Developer to CF CLI.
- Step 3: Resource Match from CF CLI to the CCNG.
- Step 4: Check file existence from the CCNG to Blobstore.
- Step 5: Upload unmatched files from CF CLI to CCNG.
- Step 6: Download cached files from Blobstore to CCNG.
- Step 7: Upload complete package from CCNG to Blobstore.
- Step 8: Download package and buildpack from Blobstore to Diego Cell (Staging).
- Step 9: Upload droplet from Diego Cell (Staging) through cc-uploader, then CCNG, to the Blobstore.
- Step 10: Download droplet from Blobstore to CCNG.

The process in which the staging process uses the blobstore is as follows:

1. **cf push:** A developer runs `cf push`.
2. **Create app:** The Cloud Foundry Command Line Interface (cf CLI) gathers local source code files and computes a checksum of each.

3. **Store app metadata:** The cf CLI makes a `resource_matches` request, which matches resources to Cloud Controller. The request lists file names and their checksums. For more information and an example API request, see [Resource Matches](#) in the TAS for VMs API documentation.
4. **Check file existence** includes the following:
  - a. The Cloud Controller makes a series of 'HEAD' requests to the blobstore to find out which files it has cached.
  - b. Cloud Controller content-addresses its cached files so that changes to a file result in it being stored as a different object.
  - c. Cloud Controller computes which files it has and which it needs the cf CLI to upload. This process can take a long time.
  - d. In response to the resource match request, Cloud Controller lists the files the cf CLI needs to upload.
5. **Upload unmatched files:** The cf CLI compresses and uploads the unmatched files to Cloud Controller.
6. **Download cached files:** Cloud Controller downloads, to its local disk, the matched files that are cached in the blobstore.
7. **Upload complete package** includes the following:
  - a. Cloud Controller compresses the newly uploaded files with the downloaded cached files in a ZIP file.
  - b. Cloud Controller uploads the complete package to the blobstore.
8. **Download package & buildpack(s):** A Diego Cell downloads the package and its buildpacks into a container and stages the app.
9. **Upload droplet** includes the following:
  - a. After the app has been staged, the Diego Cell uploads the complete droplet to 'cc-uploader'.
  - b. 'cc-uploader' makes a multi-part upload request to upload the droplet to Cloud Controller.
  - c. Cloud Controller enqueues an asynchronous job to upload to the blobstore.
10. **Download droplet** includes the following:
  - a. A Diego Cell attempts to download the droplet from Cloud Controller into the app container.
  - b. Cloud Controller asks the blobstore for a signed URL.
  - c. Cloud Controller redirects the Diego Cell droplet download request to the blobstore.
  - d. A Diego Cell downloads the app droplet from the blobstore and runs it.

## Blobstore Cleanup

**How Cloud Controller reaps expired packages, droplets, and buildpacks**

As new droplets and packages are created, the oldest ones associated with an app are marked as `EXPIRED` if they exceed the configured limits for packages and droplets stored per app.

Each night, starting at midnight, Cloud Controller runs a series of jobs to delete the data associated with expired packages, droplets, and buildpacks.

Enabling the native versioning feature on your blobstore increases the number of resources stored and costs. For more information, see [Using Versioning](#) in the AWS documentation.

## Automatic Orphaned Blob Cleanup

Orphaned Blobs are blobs that are stored in the blobstore, but which Cloud Controller does not list in its database. These are distinct from [Expired Blobs](#), which Cloud Controller can still link to a particular package, droplet, or buildpack.

Orphaned Blobs are typically created after a blob deletion fails silently or something else goes wrong.

Cloud Controller detects and removes Orphaned Blobs by scanning part of the blobstore daily and checking for any blobs that its database does not account for. The process scans through the entire blobstore every week, and only removes blobs that show as orphans for three consecutive days.

Cloud Controller performs this automatic cleanup when the `cloud_controller_worker` job property `cc.perform_blob_cleanup` is set to `true`.

Two instances of Cloud Foundry should **not** use the same blobstore buckets, as the uploaded blobs will be marked as 'orphaned' by the other Cloud Foundry instance and deleted.

## Manual blob cleanup

Cloud Controller does not track resource cache and buildpack cache blob-types in its database, so it does not [reap them automatically](#) as it does with app package, buildpack, and droplet type blobs.

To clean up the buildpack cache, admin users can run `cf curl -X DELETE /v2/blobstores/buildpack_cache`. This empties the buildpack cache completely, which is a safe operation.

To clean up the resource cache, delete it as follows:

- **Internal blobstore:** Run `bosh ssh` to connect to the blobstore VM (NFS or WebDav) and `rm *` the contents of the `/var/vcap/store/shared/cc-resources` directory.
- **External blobstore:** Use the file store's API to delete the contents of the `resources` bucket.

Do not manually delete app package, buildpack, or droplet blobs from the blobstore. To free up resources from those locations, run `cf delete-buildpack` for buildpacks or `cf delete` for app packages and droplets.

## Blobstore load

The load that Cloud Controller generates on its blobstore is unique due to resource matching. Many blobstores that perform well under normal read, write, and delete loads are overwhelmed by Cloud Controller's heavy use of HEAD requests during resource matching.

Pushing an app with large number of files causes Cloud Controller to check the blobstore for the existence of each file.

Parallel BOSH deployments of Diego Cells can also generate significant read load on the Cloud Controller blobstore as the cells perform evacuation. For more information, see the [Evacuation](#) section of the *App Container Lifecycle* topic.

## Blobstore interaction timeouts

Cloud Controller inherits default blobstore operation timeouts from Excon. Excon defaults to 60 second read, write, and connect timeouts.

For more information, see the [excon](#) repository on GitHub.

## Garden components

You can use Garden, the component that VMware Tanzu Application Service for VMs (TAS for VMs) uses to create and manage isolated environments called containers. Each instance of an app deployed to TAS for VMs runs within a container.

For more information about how containers work, see [Container Mechanics](#) in *Container Security*.

## Plug-in back ends

Garden has plug-in back ends for different platforms and runtimes. It specifies a set of interfaces that each platform specific back end must implement.

These interfaces contain methods to perform the following actions:

- Create and delete containers.
- Apply resource limits to containers.
- Open and attach network ports to containers.
- Copy files into and out of containers.
- Run processes within containers.
- Stream `STDOUT` and `STDERR` data out of containers.
- Annotate containers with arbitrary metadata.
- Snapshot containers for redeploys without downtime.

For more information, see the [Garden](#) repository on GitHub.

## Garden-runC back end

TAS for VMs currently uses the Garden-runC back end, a Linux-specific implementation of the Garden interface using the [Open Container Interface](#) (OCI) standard. Previous versions of TAS for VMs used the Garden-Linux back end. For more information, see the [Garden-Linux](#) repository on GitHub.

Garden-runC has the following features:

- Uses the same OCI low-level container execution code as Docker and Kubernetes, so container images run identically across all three platforms
- [AppArmor](#) is configured and enforced by default for all unprivileged containers
- Seccomp allowlisting restricts the set of system calls a container can access, reducing the risk of container breakout
- Allows plug-in networking and rootfs management

For more information, see the [Garden-runC](#) repository on GitHub.

## Garden RootFS plug-in

Garden manages container file systems through a plug-in interface. TAS for VMs uses the Garden RootFS (GrootFS) plug-in for this task. GrootFS is a Linux-specific implementation of the Garden volume plug-in interface.

GrootFS performs the following actions:

- Creates container file systems based on buildpacks and droplets.
- Creates container file systems based on remote docker images.
- Authenticates with remote registries when using remote images.
- Properly maps UID/GID for all files inside an image.
- Runs garbage collection to remove unused volumes.
- Applies per container disk quotas.
- Provides per container disk usage stats.

For more information, see [GrootFS Disk Usage](#) and the [GrootFS repository](#) on GitHub.

## GrootFS disk usage in Cloud Foundry

This topic tells you about the concepts related to GrootFS disk space management in VMware Tanzu Application Service for VMs (TAS for VMs).

## GrootFS stores

GrootFS is the container root filesystem management component for Garden. A container root filesystem or *rootfs* is often referred to as an **image**.

A **GrootFS store** is the directory in which rootfs layers and container images are cached. This directory is configured by GrootFS and mounted on an XFS-formatted volume by the Garden job during BOSH VM creation.

Individual container root filesystems are provided via OverlayFS mounts.

Supplying GrootFS with an already formatted XFS volume for its' store is not yet supported for BOSH-controlled deployments.

## Garbage collection behavior in GrootFS stores

GrootFS stores are initialized to use the entirety of `/var/vcap/data`. If the `reserved_space_for_other_jobs_in_mb` is not set high enough, or if there are many images with few shared volumes, the store can use up all available space.

The thresholder component calculates and sets a value so that GrootFS's garbage collector can attempt to ensure that a small reserved space is kept free for other jobs. GrootFS only tries to garbage collect when that threshold is reached. However, if all the rootfs layers are actively in use by images, then garbage collection cannot occur and that space is used up.

## Volumes

Underlying layers in rootfs images are known as `volumes` in GrootFS. They are read-only and their changesets are layered together through an **OverlayFS** mount to create the root filesystems for containers.

When GrootFS writes each filesystem volume to disk, it also stores the number of bytes written to a file in a `meta` directory. The size of an individual volume is available in its corresponding metadata file. GrootFS also stores the SHA of each underlying volume used by an image in the `meta` folder.

For each container, GrootFS mounts the underlying `volumes` using overlay to a point in the `images` directory. This mount point is the rootfs for the container and is read write.

On disk, the read-write layer for each container can be found at

`/var/vcap/data/grootfs/store/unprivileged/images/CONTAINER-ID/diff` (or  
`/var/vcap/data/grootfs/store/privileged/images/CONTAINER-ID/diff` for privileged containers.)

When GrootFS calls on the built-in XFS quota tooling to get disk usage for a container, it takes into account data written to those `diff` directories and not the data in the read-only volumes.

## Volume Cleanup Example

When `clean` is called in GrootFS, any layers that are not being used by an existing rootfs are deleted from the store. The cleanup only takes into account the `volumes` folders in the store.

For example, imagine that there are two rootfs images from different base images, Image A and Image B:

```
- Image A
  Layers:
    - layer-1
    - layer-2
    - layer-3

- Image B
  Layers:
    - layer-1
    - layer-4
    - layer-5
```

They have a layer in common, layer-1. And after deleting Image B, layer-4 and layer-5 can be collected by `clean`, but not layer-1 because Image A still uses that layer.

For more information on how to calculate GrootFS disk usage in your deployment, see [Examining GrootFS Disk Usage](#).

## Additional information

For more information, see the following sections of [garden-runc-release](#):

- [overlay-xfs-setup](#)
- [grootfs-utils](#)
- [thresholder](#)

## HTTP routing

This topic tells you how the Gorouter, the main component in the VMware Tanzu Application Service for VMs (TAS for VMs) routing tier, routes HTTP traffic within TAS for VMs.

For more information about routing, see [Routing in TAS for VMs Components](#).

## HTTP headers

### Header size limit

The Gorouter has a limit of 1 MB for HTTP Headers.

The specific language, framework, and configuration of the back end app container determine the effective header size limit. For example, the default header size for the Tomcat container is 8 kB.

### X-Forwarded Proto

The [X-Forwarded-Proto](#) header gives the scheme of the HTTP request from the client.

If an incoming request includes the [X-Forwarded-Proto](#) header, the Gorouter:

- Appends it to the existing header.
- Sets the scheme to HTTP if the client made an insecure request, meaning a request on port [80](#).
- Sets the scheme to HTTPS if the client made a secure request, meaning a request on port [443](#).

Developers can configure their apps to reject insecure requests by inspecting the [X-Forwarded-Proto](#) HTTP header on incoming traffic. The header might have multiple values represented as a comma-separated list, so developers must ensure the app rejects traffic that includes any [X-Forwarded-Proto](#) values that are not HTTPS.

### X-Forwarded-For

If [X-Forwarded-For](#) is present, the Gorouter appends the load balancer's IP address to it and forwards the list. If [X-Forwarded-For](#) is not present, the Gorouter sets it to the IP address of the load balancer in the forwarded request (some load balancers masquerade the client IP). If a load balancer sends the client IP using the PROXY protocol, then the Gorouter uses the client IP address to set [X-Forwarded-For](#).

If your load balancer terminates TLS on the client side of the Gorouter, it must append these headers to requests forwarded to the Gorouter. For more information, see [Securing Traffic into TAS for VMs](#).

### HTTP headers for Zipkin tracing

Zipkin is a tracing system that allows app developers to troubleshoot failures or latency issues. Zipkin provides the ability to trace requests and responses across distributed systems. For more information about Zipkin tracing, see [Zipkin.io](#).

When Zipkin tracing is enabled in TAS for VMs, the Gorouter examines the HTTP request headers and performs the following:

- If the `X-B3-TraceId` and `X-B3-SpanId` HTTP headers are not present in the request, the Gorouter generates values for these and inserts the headers into the request forwarded to an app. The Gorouter access log message for the request includes `x_b3_traceid` and `x_b3_spanid`.
- If the `X-B3-TraceId` and `X-B3-SpanId` HTTP headers are present in the request, the Gorouter forwards them unmodified. In addition to these trace and span IDs, the Gorouter access log message for the request includes `x_b3_parentspanid`.

You can then add Zipkin trace IDs to app logs in order to trace app requests and responses in TAS for VMs.

After adding Zipkin HTTP headers to app logs, you can correlate the trace and span IDs that the Gorouter logs with the trace IDs that the app logs by running `cf logs APP-NAME`, where `APP-NAME` is the name of the app. To correlate trace IDs for a request through multiple apps, each app must forward appropriate values for the headers with requests to other apps.

For more information about Zipkin tracing, see [Enabling Zipkin Tracing](#).

## HTTP headers for W3C tracing

Similar to Zipkin, W3C is a tracing specification that allows app developers to monitor and profile requests and responses.

When W3C tracing is enabled in TAS for VMs, the Gorouter generates W3C HTTP headers unless they are provided by the client, as described in [Unique trace identification](#). For more information about W3C tracing, see the w3.org [Trace Context](#) standard.

You can add W3C trace IDs to app logs to trace app requests and responses in TAS for VMs.

After adding W3C HTTP headers to app logs, you can correlate the W3C trace IDs that the Gorouter logs with the W3C trace IDs that the app logs by running:

```
cf logs APP-NAME
```

Where `APP-NAME` is the name of the app.

To correlate W3C trace IDs for a request through multiple apps, each app must forward appropriate values for the headers with requests to other apps.

## HTTP headers for app instance routing

If you want to retrieve debug data for a specific instance of an app, you can use the HTTP header `x-cf-App-Instance` to make a request to the app instance you want to debug.

To make an HTTP request to a specific app instance:

1. In a terminal window, retrieve the global unique identifier (GUID) of your app by running:

```
cf app APP-NAME --guid
```

Where `APP-NAME` is the name of your app.

2. From the terminal output, record the GUID of your app.
3. List your app instances and retrieve the index number of the instance you want to debug by running:

```
cf app APP-NAME
```

Where `APP-NAME` is the name of your app.

4. From the terminal output, record the the index number of the instance you want to debug.
5. Make a request to the app route by running:

```
curl APP-FQDN -H "X-Cf-App-Instance": "APP-GUID:INSTANCE-INDEX-NUMBER"
```

Where:

- `APP-FQDN` is the fully-qualified domain name (FQDN) of your app. For example, `app.example.com`.
- `APP-GUID` is the app GUID that you recorded in a previous step.
- `INSTANCE-INDEX-NUMBER` is the instance index number that you recorded in the previous step.

You can only use `X-Cf-App-Instance` header on the Diego architecture.

If either of the values you provide in the above command are invalid, Gorouter returns a `400` error, and the response from Gorouter contains a `X-Cf-Routererror` header with more information about the error. The following table describes the possible error responses:

X-Cf-Routererror Value	Reason for Error	Response Body
<code>invalid_cf_app_instance_header</code>	The value provided for <code>X-Cf-App-Instance</code> includes an incorrectly formatted app GUID.	None
<code>unknown_route</code>	The value provided for <code>X-Cf-App-Instance</code> includes a correctly formatted app GUID, but the app instance index number was not found for the requested route.	400 Bad Request: Requested instance ('1') with guid ('aaaaaaaaaaaa-aaaa-aaaa-aaaaaaaaaaaaaa') does not exist for route ('example-route.cf.example.com')

The `X-Cf-App-Instance` header is not effective for applications that have a route service configured.

The `X-Cf-App-Instance` header is not supported for multi-process apps or apps that have undergone a [rolling or canary deployment](#). For these apps, use the `X-Cf-Process-Instance` header instead.

## HTTP headers for process instance routing

The `X-Cf-Process-Instance` header requires routing-release 0.332.0 or higher.

Apps that have [multiple processes](#) or apps that have been pushed with the rolling or canary deployment strategies cannot be reliably routed to using the `X-Cf-App-Instance` header. Users who wish to route to a specific instance of these apps should use the `X-Cf-Process-Instance` header.

To make an HTTP request to a specific process instance:

1. In a terminal window, retrieve the global unique identifier (GUID) of your app by running:

```
cf app APP-NAME --guid
```

Where `APP-NAME` is the name of your app.

2. From the terminal output, record the GUID of your app.
3. Retrieve the process GUIDs for your app by running:

```
cf curl /v3/<APP-GUID/processes
```

4. From the terminal output, record the GUID of the process you are interested in.
5. Make a request to the app route by running:

```
curl APP-FQDN -H "X-Cf-Process-Instance": "PROCESS-GUID"
curl APP-FQDN -H "X-Cf-Process-Instance": "PROCESS-GUID:INSTANCE-INDEX-NUMBER"
```

Where:

- `APP-FQDN` is the fully-qualified domain name (FQDN) of your app. For example, `app.example.com`.
- `PROCESS-GUID` is the process GUID that you recorded in a previous step.
- `INSTANCE-INDEX-NUMBER` is the \_optional\_ process instance index number. If `INSTANCE-INDEX-NUMBER` is omitted, then Gorouter routes to all instances of the process.

If either of the values you provide in the above command are invalid, Gorouter returns a `400` error, and the response from Gorouter contains a `X-Cf-Routererror` header with more information about the error. The following table describes the possible error responses:

X-Cf-Routererror Value	Reason for Error	Response Body
<code>invalid_cf_process_instance_header</code>	The value provided for <code>X-Cf-Process-Instance</code> includes an incorrectly formatted process GUID or index.	None
<code>unknown_route</code>	The value provided for <code>X-Cf-App-Instance</code> includes a correctly formatted app GUID, but the app instance index number was not found for the requested route.	<code>400 Bad Request: Requested instance ('1') with process guid ('aaaaaaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa') does not exist for route ('example-route.cf.example.com')</code>

## Forwarding client certificate to apps

Apps that require mutual TLS (mTLS) need metadata from client certificates to authorize requests. TAS for VMs supports this use case without bypassing layer-7 load balancers and the Gorouter.

The HTTP header `X-Forwarded-Client-Cert` (XFCC) might be used to pass the originating client certificate along the data path to the app. Each component in the data path must trust that the back-end component has not allowed the header to be tampered with.

If you configure the load balancer to terminate TLS and set the XFCC header from the received client certificate, you must also configure the load balancer to strip this header if it is present in client requests. This configuration is required to prevent spoofing of the client certificate.

The following sections describe supported deployment configurations.

### Terminate TLS at Load Balancer

By default, the Gorouter forwards arbitrary headers that are not otherwise mentioned in the docs. This includes the XFCC header.

For apps to receive the XFCC header, configure your load balancer to set the XFCC header with the contents of the client certificate received in the TLS handshake.

To enable this mode:

1. Go to Tanzu Operations Manager Installation Dashboard.
2. Click the TAS for VMs tile.
3. Select **Networking**.
4. Under **TLS termination point**, select **Infrastructure load balancer**.

### Terminate TLS at the Gorouter

If the Gorouter is the first component to stop TLS, such that it receives the certificate of the originating client in the mutual TLS handshake, select this option. When selected, the Gorouter sets the XFCC header to the contents of the client certificate received in the TLS handshake and strips the XFCC header when present in a request.

This option requires you to configure the load balancer in front of the Gorouter to pass through TLS handshake to the Gorouter through TCP.

To enable this mode:

1. Go to Tanzu Operations Manager Installation Dashboard.
2. Click the TAS for VMs tile.
3. Select **Networking**.
4. Under **TLS termination point**, select **Gorouter**.

The Gorouter trusts the Diego intermediate certificate authority. This trust is enabled automatically and permits mutual authentication between apps running on Operations Manager.

## Client-Side TLS

Depending on your needs, you can configure your TAS for VMs deployment to terminate TLS at the Gorouter, at the Gorouter and the load balancer, or at the load balancer only. For more information, see [Securing Traffic into TAS for VMs](#).

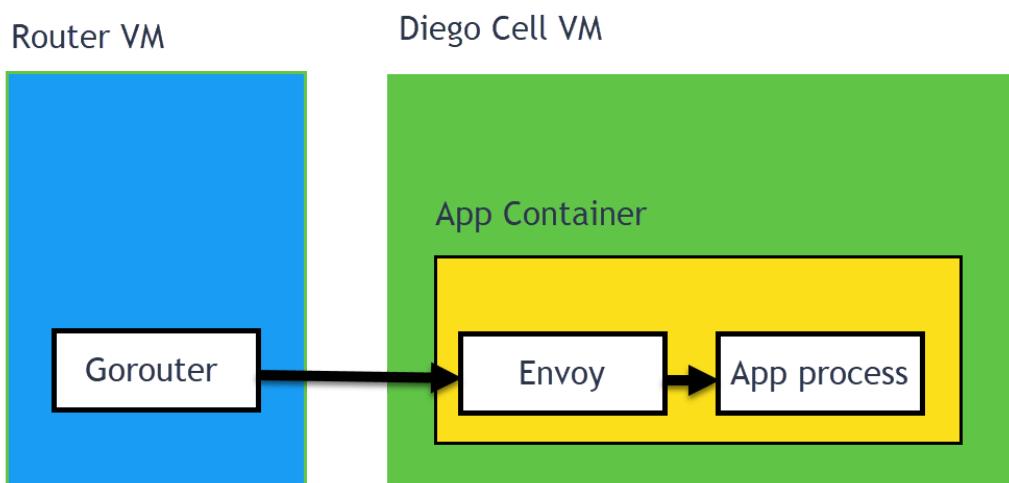

## TLS to apps and other back end services

The Gorouter supports TLS and mutual authentication to back-end destinations, including app instances, platform services, and any other routable endpoints.

This has the following benefits:

- Improved availability for apps by keeping routes in the Gorouter's routing table when TTL expires
- Increased guarantees against mis-routing by validating the identity of back ends before forwarding requests
- Increased security by encrypting data in flight from the Gorouter to back ends

The TLS (or MTLS) traffic from Gorouter to the app backend “just works.” There is nothing that the app has to do. Gorouter does not talk directly to the backend app, but communicates with the Envoy sidecar. There is an Envoy sidecar in every app container. The Envoy sidecar has the correct certificates needed, so Gorouter and the Envoy communicate using TLS (or MTLS, depending on the configuration). Then the Envoy sidecar proxies the unencrypted traffic directly to the app process. For more information, see [Envoyproxy.io](#).

## Preventing mis-routes

As TAS for VMs manages and balances apps, the internal IP address and ports for app instances change. To keep the Gorouter's routing tables current, a Route-Emitter on each Diego Cell sends periodic messages for each app instance running on that Diego Cell to all Gorouters through NATS. Each message includes the location and a unique identifier for the app instance to verify its identity when using TLS to communicate with the instance.

Network partitions or NATS failures can cause the Gorouter's routing table to fall out of sync, as TAS for VMs continues to re-create containers across hosts to keep apps running. This can lead to routing of requests to incorrect destinations.

Before forwarding traffic to an app instance, the Gorouter initiates a TLS handshake with an Envoy proxy running in each app container. In the TLS handshake, the Envoy proxy presents a certificate generated by Diego for each container that uniquely identifies the container using the same app instance identifier sent by the Route-Emitter, configured in the certificate as a domain Subject Alternative Name (SAN). For more information, see [Envoyproxy.io](#).

If the Gorouter confirms that the app instance identifier in the certificate matches the one received in the route registration message, the Gorouter forwards the HTTP request over the TLS session, and the Envoy proxy then forwards it to the app process. If the instance identifiers do not match, the Gorouter removes the app instance from its routing table and transparently retries another instance of the app.

Currently, only Linux cells support the Gorouter validating app instance identities using TLS by default. With Windows cells, the Gorouter connects to back ends without TLS, forwarding requests to Windows apps over plain text and pruning based on route TTL.

## Configuring validation of app instance identity with TLS

Verifying app identity using TLS improves resiliency and consistency for app routes.

The **App Containers** pane of the TAS for VMs tile includes these options under **Gorouter app identity verification**:

- **The Gorouter uses TLS to verify app identity:** The Gorouter verifies app identity using TLS. This option is selected by default.
- **The Gorouter and apps use mutual TLS to verify each other's identity:** The Gorouter and your apps verify each other's identity using TLS.

If you configure mutual TLS app identity verification, app containers accept incoming communication only from the Gorouter. This deactivates TCP routing.

To allow TLS communications to back ends running on Windows cells, you can configure the same options under **Gorouter app identity verification (beta)** in the **Advanced Features** pane of the VMware Tanzu Application Service for VMs [Windows] (TAS for VMs [Windows]) tile.

## Router balancing algorithm

Gorouter can be configured to use different load balancing algorithms for routing incoming requests to app instances. The Gorouter maintains a dynamically updated list of app instances for each route. Depending on which algorithm is selected, it forwards to one of the app instances.

As a platform operator, you can configure the behavior by changing the value of `router.balancing_algorithm` manifest property.

The possible options:

- `round-robin`. For more information, see [Round-Robin Load Balancing](#).
- `least-connection`. For more information, see [Least-Connection Load Balancing](#).

By default, the Gorouter uses the round-robin algorithm.

The balancing algorithm behavior can optionally be further fine-tuned by changing the value of `router.balancing_algorithm_az_preference` to either of the following options:

- `none`
- `locally-optimistic`

By default, the Gorouter's balancing algorithm availability zone preference is None. We do not recommend changing this value. For more information about these values, see [Load Balancing AZ Preference](#).

## Round robin load balancing

Incoming requests for a given route are forwarded to all app instances one after another, looping back to the first one after they have each received a request. This algorithm is suitable for most use cases and evenly distributes the load between app instances.

## Least connection load balancing

Each request for a given route is forwarded to the app instance with the least number of open connections. This algorithm can be more suitable for some cases. For example, if app instances have long-lived connections and are scaled up, then new instances receive fewer connections, causing a disproportionate load. In this case, choosing a least-connection algorithm sends new connections to new instances to equalize the load.

## Load balancing availability zone preference

The Gorouter has the ability to try to pick from app instances that are present in the same availability zone as the Gorouter itself. By default, the Gorouter has no preference, and will use the configured balancing algorithm across all possible app instances in all existing availability zones.

If the gorouter availability zone preference is set to `locally-optimistic`, then for each request, on the initial attempt to pick an app instance, the Gorouter will use the configured balancing algorithm across all instances in the same availability zone as the Gorouter itself. Subsequent retries, in the case of failure or unavailability, will use instances in all available availability zones.

## WebSockets

WebSockets is a protocol providing bi-directional communication over a single, long-lived TCP connection, commonly implemented by web clients and servers. WebSockets are initiated through HTTP as an upgrade request. The Gorouter supports this upgrade handshake and holds the TCP connection open with the selected app instance.

To support WebSockets, the operator must configure the load balancer correctly. Depending on the configuration, clients may have to use a different port for WebSocket connections, such as port 4443, or a different domain name. For more information, see [Supporting WebSockets](#).

## Session affinity

Gorouter supports session affinity, or *sticky sessions*, for incoming HTTP requests to compatible apps.

With sticky sessions, when multiple instances of an app are running on TAS for VMs, requests from a particular client always reach the same app instance. This allows apps to store session data specific to a user session.

To support sticky sessions, configure your app to return a sticky session cookie in responses. The default value for this field is `JSESSIONID`. You can configure the cookie names that the routing tier uses for sticky sessions. To configure the names of the cookies, see [Configure Networking](#) in *Configuring TAS for VMs*.

If an app returns a sticky session cookie to a client request, the TAS for VMs routing tier generates a unique `VCAP_ID` for the app instance based on its GUID with the same expiry, sameSite, and secure attributes as `JSESSIONID`. For example:

```
323f211e-fa3-4161-9bd1-615392327913
```

On subsequent requests, the client must provide both the sticky session and `VCAP_ID` cookies.

CF routing tier uses the `VCAP_ID` cookie to forward client requests to the same app instance every time. The sticky session cookie is forwarded to the app instance to enable session continuity. If the app instance identified by the `VCAP_ID` crashes, the Gorouter attempts to route the request to a different instance of the app. If the Gorouter finds a healthy instance of the app, it initiates a new sticky session.

TAS for VMs does not persist or replicate HTTP session data across app instances. If an app instance crashes or is stopped, the session data for that instance is lost. If you require session data to persist across crashed or stopped instances, or to be shared by all instances of an app, store the session data in a TAS for VMs marketplace service that offers data persistence.

For more information, see [Session Affinity](#) on GitHub.

## Keep alive connections

### Front end clients

Gorouter supports keep alive connections from clients and does not close the TCP connection with clients immediately after returning an HTTP response. Clients are responsible for closing these connections.

### Back end servers

If keep-alive connections are disallowed, the Gorouter closes the TCP connection with an app instance or system component after receiving an HTTP response.

If keep-alive connections are allowed, the Gorouter maintains established TCP connections to back ends. The Gorouter supports up to 100 idle connections to each back end:

- If an idle connection exists for a given back end, the Gorouter reuses it to route subsequent requests.
- If no idle connection exists for this back end, the Gorouter creates a new connection.

## Transparent retries

If the Gorouter cannot establish a TCP connection with a selected app instance, the Gorouter considers the instance ineligible for requests for 30 seconds and transparently attempts to connect to another app

instance. Once the Gorouter has established a TCP connection with an app instance, the Gorouter forwards the HTTP request.

When you deploy an app that requires Diego Cells to restart or recreate, the app might not respond to a Gorouter request before the keep-alive connection breaks. The following table describes how the Gorouter behaves if it cannot establish a TCP connection to an app:

If the Gorouter...	and the back end...	then the Gorouter...
cannot establish a TCP connection to a back end	N/A	retries another back end no more than three times (3 times is the default. Operators can configure a different maximum.)
establishes a TCP connection to a back end and forwards the request	does not respond	waits 15 minutes for a response, and if it receives an error, does not retry another back end
establishes a TCP connection to a back end and forwards the request	returns a TCP connection error	returns an error to the client, marks the back end ineligible, and does not retry another back end

In all cases, if the app still does not respond to the request, the Gorouter returns a [502](#) error. For more information, see [Troubleshooting Router Error Responses](#).

## User Accounts and Authentication overview

Cloud Foundry User Account and Authentication (UAA) is an open-source identity server project under the Cloud Foundry Foundation.

UAA provides enterprise-scale identity management features. It is used by these commercial services, for example:

- [Single sign-on for VMware Tanzu](#): Identity services for apps and APIs running on VMware Tanzu Application Service (TAS for VMs)
- [SAP Cloud Identity Services](#)

## What is UAA?

UAA provides identity based security for apps and APIs. It supports open standards for authentication and authorization, including:

- OAuth
- OpenID Connect
- SAML
- LDAP
- SCIM

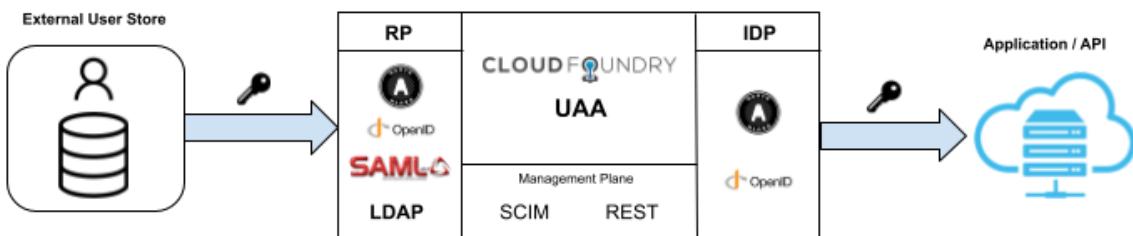

The major features of UAA include:

- User Single Sign-On (SSO) using federated identity protocols
- API security with OAuth
- User and group management
- Multi-tenancy support

- Support for **JWT** and **opaque** as a token format
- Token revocation
- Operational flexibility
  - Operate and run as a **BOSH release**, which uses multi-cloud deployment capabilities
  - Push as an app to TAS for VMs
- Database flexibility, including support for MySQL and Postgres
- Auditing, logging, and monitoring
- Token exchange for SAML and JWT bearers
- Rest APIs for authentication, authorization, and configuration management

## UAA architecture

The following diagram illustrates the architecture of UAA:

The following table describes the protocols UAA can use:

Protocol	Purpose	Profiles
OAuth 2.0	Authorizes apps and APIs	Authorization Server, Relying Party
OpenID Connect 1.0	Federates to external identity providers (IDPs) and acts as an IDP for SSO	Identity Provider, Relying Party
SAML 2.0	Federates to external IDPs	Service Provider
LDAP	Authenticates users in external user store	LDAP Client
SCIM 1.0	Manages users and groups	Identity Provisioning

## Client-side tools and libraries

The following table describes the client-side tools and libraries UAA uses:

Name	Language
UAAC	Ruby
CF-UAA-LIB	
Spring Security OAuth	Java

Name	Language
CF Java Client	Java
UAA Javascript SDK (Singular)	JS

## The role of UAA in securing TAS for VMs

TAS for VMs relies on UAA for identity and access management requirements. UAA secures user and system access to TAS for VMs installations.

Since TAS for VMs is primarily used in the enterprise context, UAA supports enterprise SSO workflows. If you have already authenticated against the enterprise IDP, you can access TAS for VMs without entering credentials again.

Some of the major components of TAS for VMs that use UAA include:

- Cloud Controller
- Gorouter
- Loggregator
- Container networking

Each of these components expose APIs for user and system interaction. UAA uses OAuth to secure the APIs exposed by core TAS for VMs components.

UAA secures many different TAS for VMs components, including:

- Cloud Foundry Command Line Interface (cf CLI)
- Cloud Controller
- Loggregator
- Notifications
- Gorouter
- Container Networking
- Diego
- BOSH Director
- Autoscaler

## Token management

After authenticating, client apps access resources and services using tokens rather than account authentication credentials. UAA generates, manages, distributes, and validates these tokens. UAA provides new tokens only to client apps with valid authentication credentials.

Once granted, token validity is unchallenged until the token expires due to timeout.

UAA distributes two types of tokens: access tokens and refresh tokens.

### Access tokens

Client apps use UAA provided access tokens to request access to API endpoints, resources, and services. The access token presented by a client app must be valid in order to access a resource.

Access tokens are valid for a short period of time.

After a UAA-provided access token has expired, a client app can request UAA provide a replacement. To request a replacement access token from UAA, a client app must present a valid refresh token.

## Refresh tokens

Client apps use UAA-provided refresh tokens to request replacements for expired access tokens. The refresh token presented by a client app must be valid in order to replace an expired access token.

Refresh tokens are valid for a long period of time.

UAA does not provide replacement refresh tokens. To obtain a new refresh token, a client app must re-authenticate.

## Token timeouts

The token interactions that are listed previously produce certain end results.

Authenticated client apps are running and interacting with services using tokens, not the service account's authentication. An admin can revoke a service account's access and privileges, but a client app running under that service account can continue to interact with the environment, unchallenged, as long as its token is valid. Therefore:

- The access token timeout is the maximum period during which an already running app can continue to access services after an admin has revoked privileges from the service account the app is running under.
- The refresh token timeout is the maximum period during which a client app can access services without re-authentication.

The default access and refresh token timeout values are the UAA token timeout values VMware recommends. Before altering token timeout settings, consider:

- Short default token timeout periods create overhead within your system.
  - A short access token timeout requires a client app to frequently request a replacement access token from the UAA server.
  - A short refresh token timeout requires frequent re-authentication, which might be impossible at the designated timeout frequency.
- Long timeout periods represent a security risk.
  - A long access token timeout allows an authenticated process to continue accessing services and resources for a long period after an admin has revoked privileges from the service account used by the process.
  - A long refresh token timeout allows an already authenticated app to continue running for a long period of time on stale authentication credentials without being challenged to re-authenticate.

Setting a long timeout period, such as one lasting days, can result in a client app running unchallenged for days.

## Services

This topic tells you about the services in VMware Tanzu Application Service for VMs (TAS for VMs).

### Services and service instances

TAS for VMs offers a marketplace of services that operators can use to provision reserved resources on demand. Marketplace services include resources such as databases on a shared or dedicated server, or accounts on a SaaS app. These resources are known as service instances and the systems that deliver and operate these resources are known as services.

For a service to be available in the Marketplace, an operator must integrate the service with TAS for VMs using APIs.

For more information about provisioning service instances and other life cycle operations, see [Managing Service Instances](#).

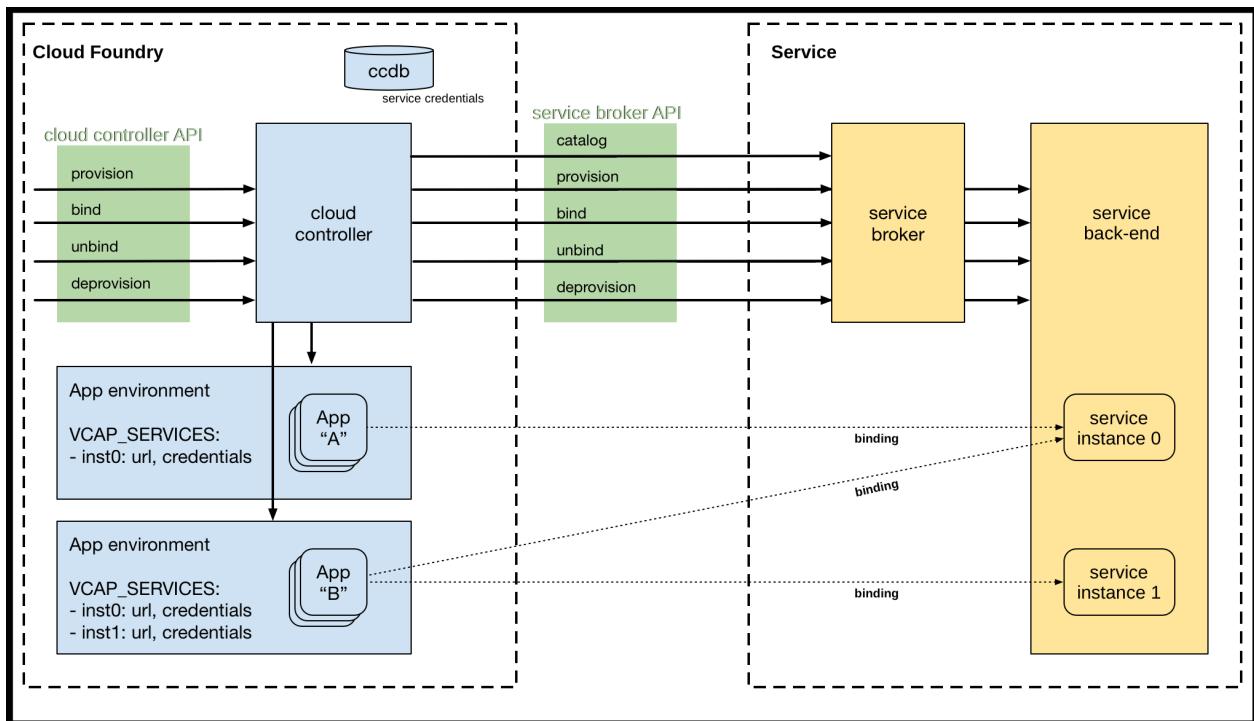

TAS for VMs enables users to use services that are not available in the Marketplace using user provided service instances (UPSI). For more information, see [User-Provided Service Instances](#).

### Architecture and terminology

Services are integrated with TAS for VMs by using a documented API for which the Cloud Controller is the client, called the Service Broker API. This cannot be confused with the Cloud Controller API (CAPI), often used to refer to the version of Cloud Foundry. The Service Broker API is versioned independently of CAPI.

The component of the service that uses the Service Broker API is called the *service broker*. This component was formerly referred to as a service gateway. However, as traffic between apps and services does not flow through the service broker, the term caused confusion. Although “gateway” still appears in old code, the term “broker” is used in conversation, in new code, and in documentation.

Service brokers advertise a catalog of service offerings and service plans, as well as interpreting calls for provision, bind, unbind, and deprovision. What a broker does with each call can vary between services. In general, ‘provision’ reserves resources on a service and ‘bind’ delivers information to an app necessary for accessing the resource. The reserved resource is called a *service instance*. What a service instance represents can vary by service. It could be a single database on a multi-tenant server, a dedicated cluster, or even an account on a web app.

## Service Instance credentials

TAS for VMs enables users to provision credentials needed to interface with a service instance. You can use app binding to deliver these credentials to your TAS for VMs app. For external and local clients, you can use service keys to generate credentials to communicate directly with a service instance.

### Binding Apps

Service instance credentials can be delivered to apps running on TAS for VMs in an environment variable. For more information, see [Delivering Service Credentials to an App](#).

For information about binding to a specific app development framework, see [Using Classic Buildpacks in Cloud Foundry](#).

### Service keys

Credentials managed manually are known as service keys. Use service keys when you want a set of credentials for use by clients other than the app in the same space. For instance, you can use service keys to connect to a service instance from a local client, or from an app in another space, or even from outside of TAS for VMs.

For more information about creating a user-provided service instance with service keys, see the [User-Provided Service Instances](#) topic. For more information about service keys, see the [Managing Service Keys](#) topic.

Not all services support service keys. Some services support credentials through app binding only.

## Implementation and deployment

How a service is implemented is up to the service provider or developer. TAS for VMs only requires that the service provider implement the Service Broker API. A broker can be implemented as a separate app, or by

adding the required HTTP endpoints to an existing service.

Because TAS for VMs only requires that a service implements the Service Broker API to be available to TAS for VMs end users, many deployment models are possible. The following are examples of valid deployment models:

- Entire service packaged and deployed by BOSH alongside TAS for VMs
- Service broker packaged and deployed by BOSH alongside TAS for VMs, rest of the service deployed and maintained by other means
- Broker (and optionally service) pushed as an app to TAS for VMs user space
- Entire service, including broker, deployed and maintained outside of TAS for VMs by other means

## Communication between Apps and Service Instances

To allow an app to communicate with a service external to TAS for VMs, you might need to configure the service to accept connections from your app based on its outbound IP address.

In your external service configuration, you must do one of the following:

- Add the entire IP address range for the Diego Cell where the app is deployed to your allow list.
- Derive the app IP address from its DNS name using a command-line tool such as `dig`, `host`, or `nslookup`. In your external service configuration, add the IP address or range of the app instance to your allow list.

## Streaming App Logs to Log Management Services

To learn how your app logs can be streamed to third-party log management services, see [Streaming App Logs to Log Management Services](#).

User provided service instances can be used to drain app logs to a service not available in the Marketplace. This is also known as setting up a syslog drain. For guidance on configuring some third party log management services, see [Service-Specific Instructions for Streaming App Logs](#).

## Managing App Requests with Route Services

To learn how Marketplace services (and user-provided service instances) can be used to perform preprocessing on app requests, see [Managing App Requests with Route Services](#).

## Migrating a Database Schema

If your app relies on a relational database, you must apply schema changes periodically. To perform database schema migrations on TAS for VMs-managed services, run a database migration task with the TAS for VMs Command Line Interface (cf CLI) tool.

For more information about running cf CLI tasks, see [Running Tasks](#).

To run tasks with the cf CLI, you must install cf CLI v6.23.0 or later. For information about downloading, installing, and uninstalling the cf CLI, see [Installing the cf CLI](#).

To run a database schema migration with the cf CLI:

1. Push the app:

```
$ cf push APP-NAME
```

Where `APP-NAME` is the name of the app.

To run a task without starting the app, you can push the app with `cf push -i 0` and then run the task. You can run the app later by scaling up the instance count.

2. Run database schema migration as a task on the app:

```
$ cf run-task APP-NAME --command "bin/rails db:migrate" --name TASK-NAME
E
Creating task for app APP-NAME in org jdoe-org / space development as j
doe@pivotal.io...
OK
Task 1 has been submitted and ran successfully.
```

Where:

- `APP-NAME` is the name of the app.
- `TASK-NAME` is the name of the task.

## CredHub

Learn about the functionality of the CredHub component.

CredHub is a component designed for centralized credential management in Operations Manager. It's a single component that can address several scenarios in the Operations Manager ecosystem. At the highest level, CredHub centralizes and secures credential generation, storage, lifecycle management, and access.

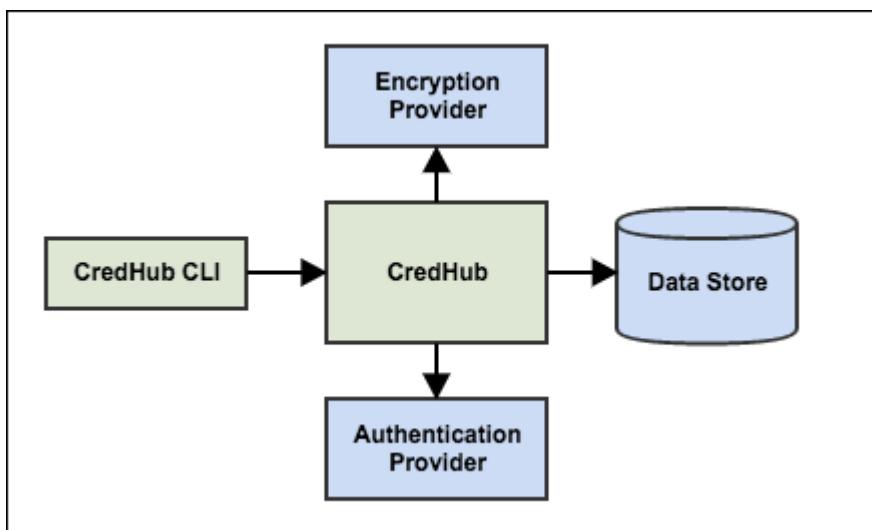

## Functions

CredHub performs a number of different functions to help generate and protect the credentials in your Operations Manager deployment:

- Securing data for storage
- Authentication
- [Authorization and Permissions](#)
- Access and change logging
- Data typing
- Credential generation
- Credential metadata
- Credential versioning

## App architecture

CredHub consists of a REST API and a CLI. CredHub is an OAuth2 resource server that integrates with User Account Authentication (UAA) to provide core authentication and federation capabilities.

## CredHub in Operations Manager

A Operations Manager deployment stores credentials in the following locations:

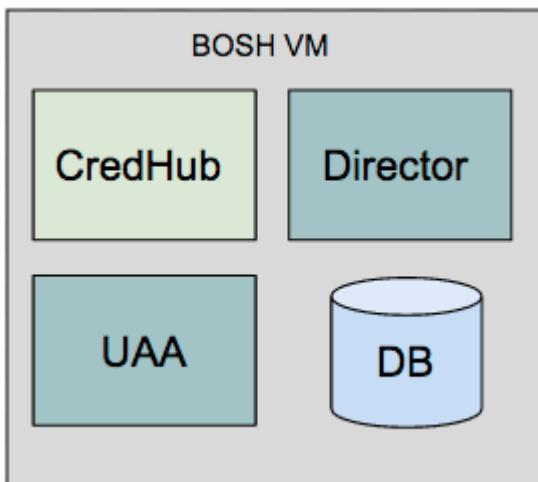

- **BOSH CredHub:** Colocated with the BOSH Director on a single VM. This CredHub instance stores credentials for the BOSH Director.
- **Runtime CredHub:** Deployed as an independent service and stores service instance credentials.

### BOSH CredHub

In Operations Manager, the BOSH Director VM includes a CredHub job. This provides a lightweight credential storage instance for the BOSH Director. The BOSH Director, VMware Tanzu Application Service for VMs (TAS for VMs), and other tiles store credentials in BOSH CredHub. For more information, see *Retrieve Credentials Stored in BOSH CredHub* in *Retrieving Credentials from Your Deployment*.

This configuration does not provide high availability.

In this colocated deployment architecture, the BOSH Director, CredHub, UAA, and the BOSH Director database are all installed on a single BOSH VM, as shown in the following diagram:

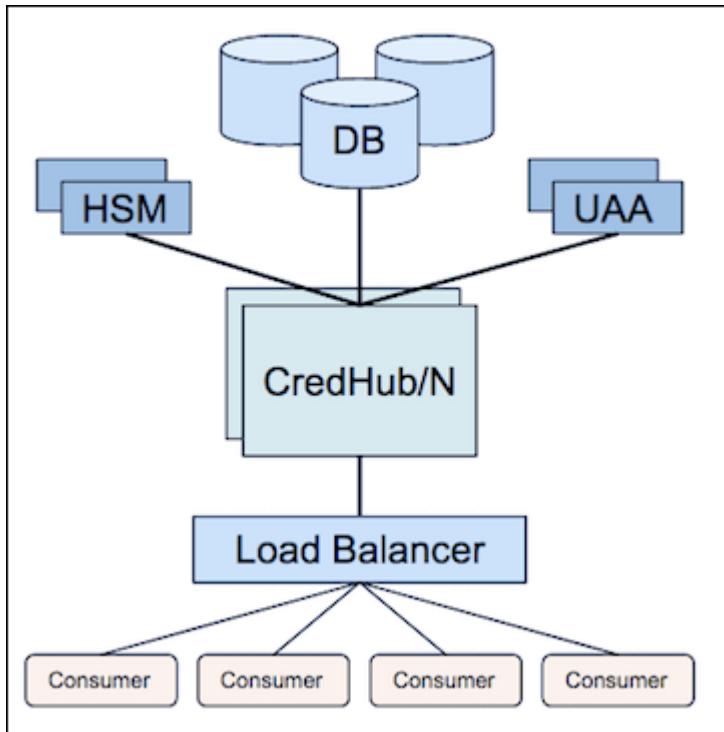

## Runtime CredHub

The TAS for VMs tile deploys CredHub as an independent service on its own VM. This provides a highly available credential storage instance for securing service instance credentials.

For more information, see [Securing Service Instance Credentials with Runtime CredHub](#).

CredHub is a stateless app, so you can scale it to multiple instances that share a common database cluster and encryption provider.

With CredHub as a service, the load balancer and external databases communicate directly with the CredHub VMs, as shown in the following diagram:

## Using CredHub to store credentials for service tiles

If you develop a service tile for Operations Manager and want to store its credentials in BOSH CredHub, see [CredHub in \*Operations Manager Tile Developer Guide\*](#).

## CredHub credential types

Credentials exist in multiple places. Components use credentials to authenticate connections between components. Installations often have hundreds of active credentials. Leaked credentials are common causes of data and security breaches, so managing them securely is very important.

For more information, see [CredHub Credential Types](#).

## Backing up and restoring CredHub instances

CredHub does not hold state, but you must ensure its dependent components are backed up. Redundant backups can help prevent data loss if an individual component fails.

For more information, see [Backing Up and Restoring CredHub Instances](#).

# App Management

## Staging your apps in Cloud Foundry

This topic tells you how Diego stages buildpack apps and Docker images in VMware Tanzu Application Service for VMs (TAS for VMs).

TAS for VMs uses Diego to manage app containers. It is a self-healing system that attempts to keep the correct number of instances running in Diego Cells to avoid network failures and crashes. For more information about Diego, see [Diego Components and Architecture](#).

Learn about tasks and long-running processes (LRPs).

For more information about these, see the [Tasks and Long-Running Processes](#) section of the *How Diego Balances App Processes* topic.

To better understand the flow and caching of source bits during staging, see the [How Staging Uses the Blobstore](#) section of the *Cloud Controller blobstore* topic.

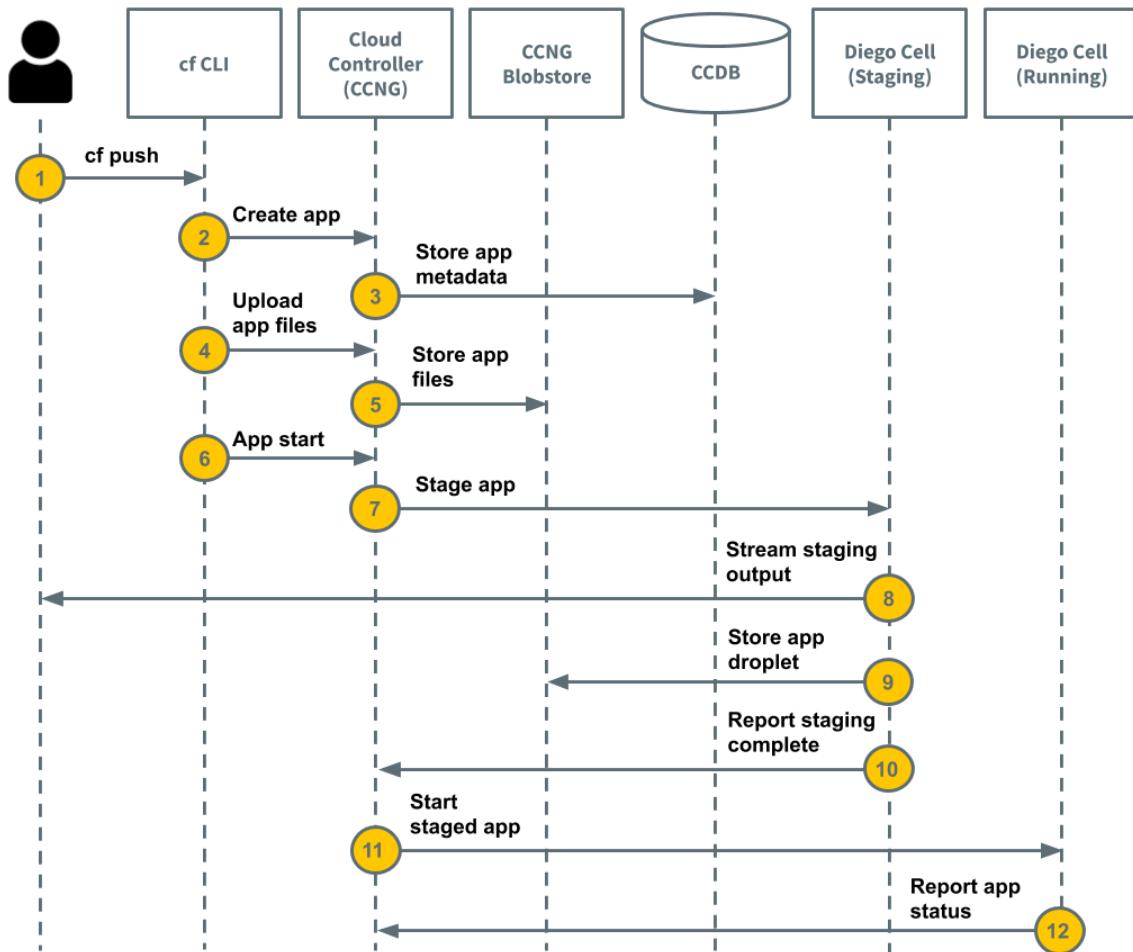

## How Diego stages buildpack apps

Learn how Diego stages buildpack apps.

The following diagram illustrates the steps and components involved in the process of staging a buildpack app. The staging process for buildpack apps includes a developer and the following components: CF Command Line, Cloud Controller (CCNG), CCNG Blobstore, CCDB, Diego Cell (Staging), and Diego Cell (Running).

- Step 1: cf push from Developer to CF Command Line.
- Step 2: Create App from CF Command Line to Cloud Controller (CCNG).
- Step 3: Stores App Metadata from CCNG to the CCDB.
- Step 4: Upload App Files from the CF Command Line to CCNG.
- Step 5: Store App Files from CCNG to CCNG Blobstore.
- Step 6: App Start from CF Command Line to CCNG.
- Step 7: Stage App from CCNG to Diego Cell (Staging).
- Step 8: Stream Staging Output from Diego Cell (Staging) to the Developer.

- Step 9: Store App Droplet from Diego Cell (Staging) to CCNG Blobstore.
- Step 10: Report Staging Complete from Diego Cell (Staging) to CCNG.
- Step 11: Start Staged App from CCNG to Diego Cell (Running).
- Step 12: Report App Status from Diego Cell (Running) to CCNG.

The following steps describe the process of staging a buildpack app:

1. A developer runs `cf push`.
2. Cloud Foundry Command Line Interface (cf CLI) tells the Cloud Controller to create a record for the app. For more information about the Cloud Controller, see [Cloud Controller](#).
3. Cloud Controller stores the app metadata. App metadata can include the app name, number of instances, buildpack, and other information about the app.
4. This step includes:
  - a. The cf CLI requests a resource match from the Cloud Controller.
  - b. The cf CLI uploads the app source files, omitting any app files that already exist in the resource cache.
  - c. The Cloud Controller combines the uploaded app files with files from the resource cache to create the app package.

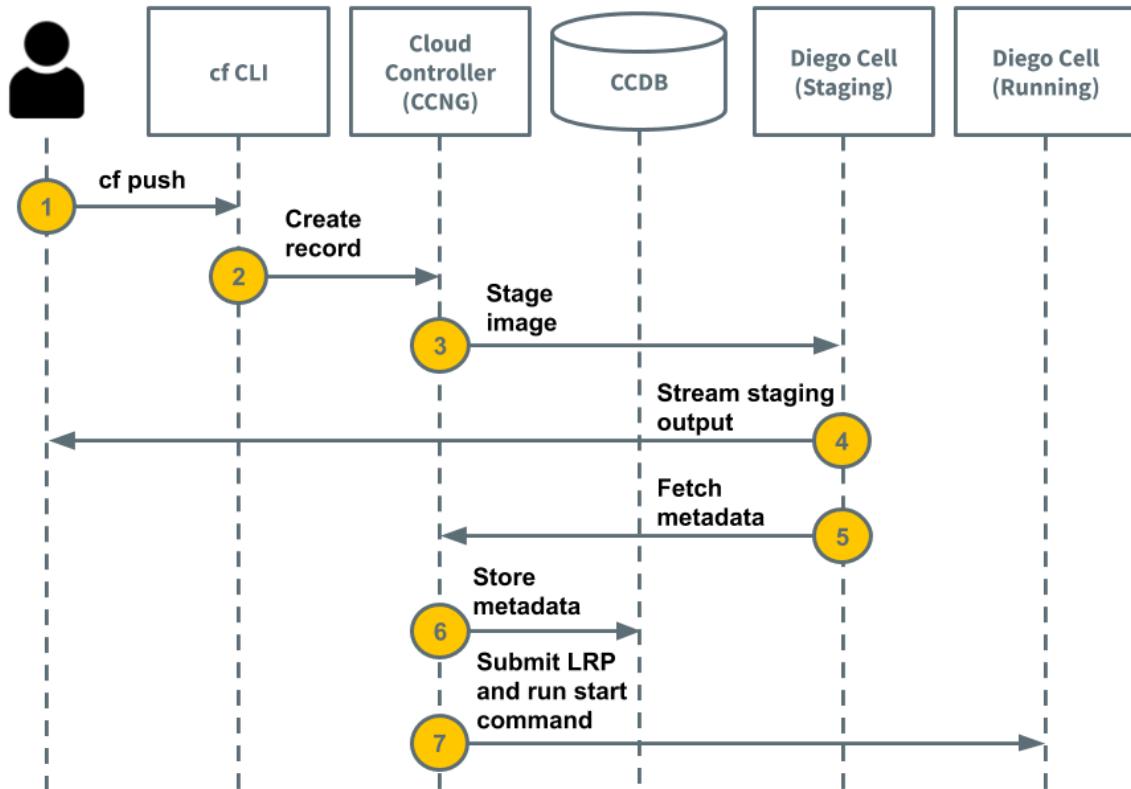

5. Cloud Controller stores the app package in the blobstore. For more information, see the [Blobstore](#) section of the *TAS for VMs Components* topic.
6. The cf CLI issues a request to start the app.
7. This step includes:
  - a. The Cloud Controller issues a staging request to Diego.
  - b. Diego schedules a Diego Cell to run the staging task.
  - c. The task downloads buildpacks and the app buildpack cache, if present.
  - d. The task uses the buildpack to compile and stage the app.
8. Diego Cell streams the output of the staging process. You might need to view the output to troubleshoot staging problems.
9. This step includes:
  - a. The task creates a tarball, or droplet, with the compiled and staged app.
  - b. The Diego Cell stores the droplet in the blobstore.
  - c. The task uploads the buildpack cache to the blobstore for use the next time the app is staged.
10. Diego Bulletin Board System (BBS) reports to the Cloud Controller that staging is complete. If staging does not complete within 15 minutes, it fails.
11. Diego schedules the app as a LRP on one or more Diego Cells.
12. Diego Cells report the status of the app to the Cloud Controller.

## How Diego stages Docker images

This section describes how Diego stages Docker images.

The following diagram illustrates the steps and components involved in the process of staging a Docker image. The staging process for Docker images includes a developer and the following components: CF Command Line, Cloud Controller (CCNG), CCDB, Diego Cell (Staging), and Diego Cell (Running).

- Step 1: CF Push from Developer to CF Command Line.
- Step 2: Create Record from CF Command Line to CCNG.
- Step 3: Stage Image from CCNG to CCDB.
- Step 4: Stream Staging Output from Diego Cell (Staging) to Developer.
- Step 5: Fetch Metadata from Diego Cell (Staging) to CCNG.
- Step 6: Store Metadata from CCNG to CCDB.
- Step 7: Submit LRP an Run Start Command from CCNG to Diego Cell (Running).

The following describe each step in the process of staging a Docker image:

1. A developer runs `cf push` and includes the name of a Docker image in an accessible Docker Registry.
2. The cf CLI tells the Cloud Controller to create a record for the Docker image.
3. This step includes:
  - a. The Cloud Controller issues a staging request to Diego.
  - b. Diego schedules a Diego Cell to run the task.
4. Diego Cell streams the output of the staging process. You might need to view the output to troubleshoot staging problems.
5. The task fetches the metadata associated with the Docker image and returns a portion of it to the Cloud Controller.
6. Cloud Controller stores the metadata in the Cloud Controller database.
7. This step includes:
  - a. Cloud Controller uses the Docker image metadata to construct a LRP that runs the start command specified in the Dockerfile.
  - b. Cloud Controller submits the LRP to Diego.
  - c. Diego schedules the LRP on one or more Diego Cells.
  - d. Cloud Controller instructs Diego and the Gorouter to route traffic to the Docker image.

Cloud Controller takes into account any user-specified overrides specified in the Dockerfile, such as environment variables.

# The app container lifecycle on Diego architecture

The life cycle stages of an application container for your VMware Tanzu Application Service for VMs (TAS for VMs) deployments running on the Diego architecture include deployment, failure events, evacuation, and shutdown.

## Deployment

App deployment involves uploading, staging, and starting the app in a container. Your app must complete each of these phases within a certain time limit. The default time limits for the phases are:

- Upload: 15 minutes
- Stage: 15 minutes
- Start: 60 seconds

Your administrator can change these default settings. Check with your administrator for the actual time limits set for app deployment.

Developers can change the time limit for starting apps through an app manifest or on the command line. For more information, see [Deploying with app manifests](#) and [Using app health checks](#).

## Crash events

If an app instance fails, TAS for VMs restarts it by rescheduling the instance on another container three times. After three failed restarts, TAS for VMs waits 30 seconds before attempting another restart. The wait time doubles each restart until the ninth restart, and remains at that duration until the 200th restart. After the 200th restart, TAS for VMs stops trying to restart the app instance.

## Evacuation

Some actions require restarting VMs with containers hosting app instances. For example, you can update stemcells or install a new version of TAS for VMs. You must restart all the VMs in a deployment.

TAS for VMs relocates the instances on VMs that are shutting down through a process called evacuation. TAS for VMs recreates the app instances on another VM, waits until they are healthy, and then shuts down the old instances. During an evacuation, you might see the app instances in a duplicated state for a brief time.

During app duplication, singleton app instances might become temporarily unavailable if the replacement instance does not become healthy within the evacuation timeout of the Diego Cell (the default is ten minutes). App developers with a low tolerance for downtime might prefer to run several instances of their app. See [Run multiple instances to increase availability](#).

## Shutdown

TAS for VMs requests a shutdown of your app instance when:

- A user runs `cf scale`, `cf stop`, `cf push`, `cf delete`, or `cf restart-app-instance`.
- A system event occurs, such as the replacement procedure during Diego Cell evacuation or when an app instance stops because of a failed health check probe.

To stop the app, TAS for VMs sends the app process in the container a SIGTERM. By default, the process has ten seconds to shut down gracefully. If the process has not exited after ten seconds, TAS for VMs sends a SIGKILL.

By default, apps must finish their in-flight jobs within ten seconds of receiving the SIGTERM before TAS for VMs stops the app with a SIGKILL. For example, a web app must finish processing existing requests and stop accepting new requests. To change the timeout period on the TAS for VMs tile or IST tile, go to the **Advanced Settings** tab and edit the “app graceful shutdown period” property. This might increase the time it takes to drain Diego Cells, which causes increased deployment time.

If your apps require a longer period of time to finish in-flight jobs and gracefully shut down, you can increase the graceful shutdown period. For more information, see [Configure Advanced Features](#) in *Configuring TAS for VMs*.

An exception to the cases previously mentioned is when monit restarts a Diego Cell replacement or Garden server that has failed. In this case, TAS for VMs immediately stops the apps that are still running using SIGKILL.

## How Diego balances app processes

Diego balances app processes over the virtual machines (VMs) in a TAS for VMs installation using the Diego Auction. When new processes need to be allocated to VMs, the Diego Auction determines which ones must run on which physical machines. The auction algorithm balances the load on VMs and optimizes app availability and resilience. This topic explains how the Diego Auction works.

For more information, see [Diego Components and Architecture](#) and the [Auction](#) repository on GitHub.

## Tasks and long running processes

Diego Auction distinguishes between two types of jobs: **Tasks** and **Long-Running Processes** (LRPs).

- **Tasks** run once, for a finite amount of time. A common example is a staging task that compiles an app’s dependencies, to form a self-contained droplet that makes the app portable and runnable on multiple VMs. Other examples of tasks include making a database schema change, bulk importing data to initialize a database, and setting up a connected service.
- **Long-Running Processes** run continuously, for an indefinite amount of time. LRPCs terminate only if they crash or are stopped. Examples include web servers, asynchronous background workers, and other applications and services that continuously accept and process input. To make high-demand LRPCs more available, Diego might allocate multiple instances of the same application to run simultaneously on different VMs, often spread across Availability Zones that serve users in different geographic regions.

Diego Auction process is repeated whenever new jobs need to be allocated to VMs. Each auction distributes a current **batch** of work, Tasks and LRPCs, that can include newly created jobs, jobs left unallocated in the previous auction, and jobs left orphaned by failed VMs. Diego does not redistribute jobs that are already running on VMs. Only one auction can take place at a time, which prevents placement collisions.

## Ordering the auction batch

Diego Auction algorithm allocates jobs to VMs to fulfill the following outcomes, in decreasing **priority** order:

1. Keep at least one instance of each LRP running.
2. Run all of the Tasks in the current batch.
3. Distribute as much of the total desired LRP load as possible over the remaining available VMs, by spreading multiple LRP instances broadly across VMs and their Availability Zones.

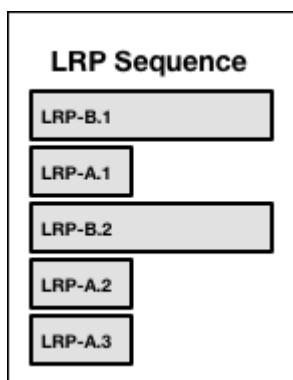

To achieve these outcomes, each auction begins with the Diego Auctioneer component arranging the batch jobs into a priority order. Some of these jobs might be duplicate instances of the same process that Diego needs to allocate for high-traffic LRPs to meet demand. The Auctioneer creates a list of multiple LRP instances based on the desired instance count configured for each process.

For more information, see the [Step 2: Passing a request to the auctioneer process](#) section of the *Diego Components and Architecture* topic.

For example, if the process LRP-A has a desired instance count of 3 and a memory load of 2, and process LRP-B has 2 desired instances and a load of 5, the Auctioneer creates a list of jobs for each process as follows:

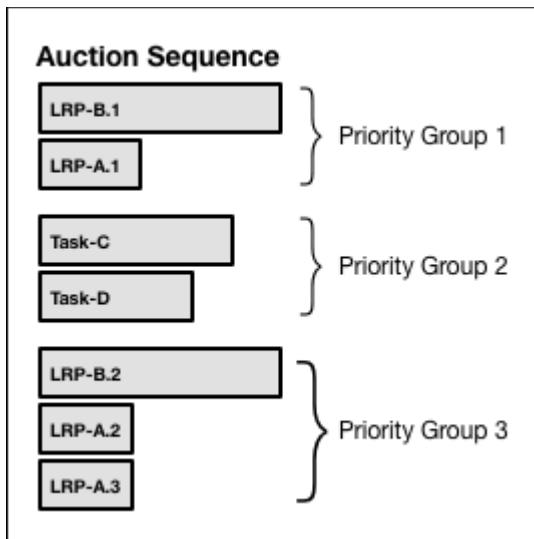

Process	Desired Instances	Load	Jobs
LRP-A	3	2	
LRP-B	2	5	

The Auctioneer then builds an ordered sequence of LRP instances by cycling through the list of LRPs in decreasing order of load. With each cycle, it adds another instance of each LRP to the sequence, until all desired instances of the LRP have been added. With the example above, the Auctioneer would order the LRPs like this:

The Auctioneer then builds an ordered sequence for all jobs, both LRPs and Tasks. Reflecting the auction batch priority order, the first instances of LRPs are first priority. Tasks are next, in decreasing order of load. Duplicate LRP jobs come last.

Adding one-time Task-C (load = 4) and Task-D (load = 3) to the above example, the priority order becomes:

The previous diagram shows the following content:

- Title: Auction Sequence
  - Priority Group 1
    - LRP-B.1 (wide box)
    - LRP-A.1 (narrow box)
  - Priority Group 2
    - Task-C (medium-wide box)
    - Task-D (narrower box)
  - Priority Group 3
    - LRP-B.2 (wide box)
    - LRP-A.2 (narrow box)
    - LRP-A.3 (narrow box)

## Auctioning the batch to the Diego Cells

With all jobs sorted in priority order, the Auctioneer allocates each in turn to one of the VMs. The process resembles an auction, where VMs “bid” with their suitability to run each job. Facilitating this process, each app VM has a resident Diego Cell that monitors and allocates the machine’s operation. The Diego Cell participates in the auction on behalf of the virtual machine that it runs on. For more information, see the [Diego Components](#) section of the *Diego Components and Architecture* topic.

Starting with the highest priority job in the ordered sequence, the Auctioneer polls all the Diego Cells on their fitness to run the currently-auctioned job.

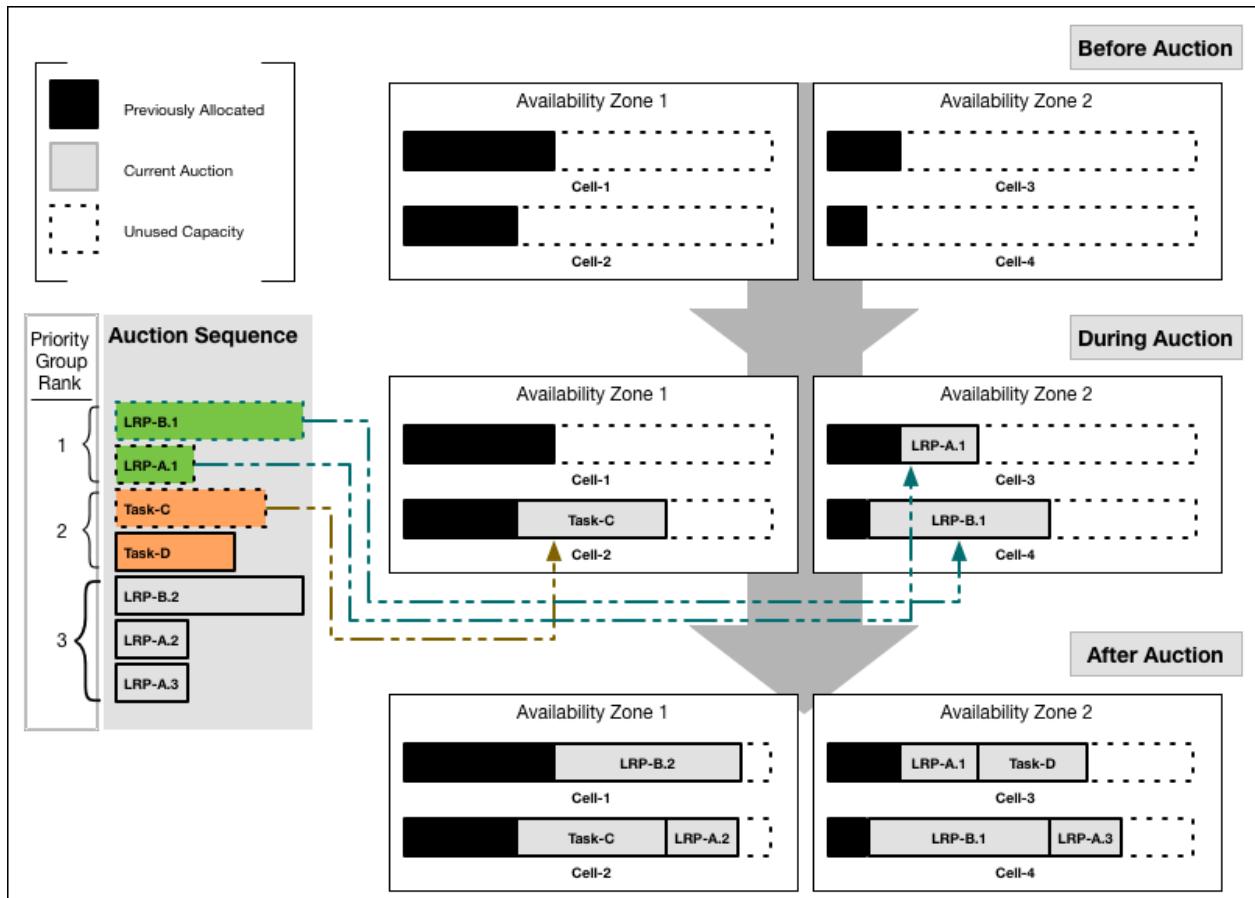

Diego Cells “bid” to host each job according to the following priorities, in decreasing order:

1. Allocate all jobs only to Diego Cells that have the correct software stack to host them, and sufficient resources given their allocation so far during this auction.
2. Allocate LRP instances into Availability Zones that are not already hosting other instances of the same LRP.

3. Within each Availability Zone, allocate LRP instances to run on Diego Cells that are not already hosting other instances of the same LRP.
4. Allocate any job to the Diego Cell that has lightest load, from both the current auction and jobs it has been running already. In other words, distribute the total load evenly across all Diego Cells.

This example auction sequence has seven jobs: five LRP instances and two Tasks.

The following diagram shows how the Auctioneer might distribute this work across four Diego Cells running in two Availability Zones:

If the Auctioneer reaches the end of its sequence of jobs, having distributed all jobs to the Diego Cells, it submits requests to the Diego Cells to run their allotted work. If the Diego Cells run out of capacity to handle all jobs in the sequence, the Auctioneer carries the unallocated jobs over and merges them into the next auction batch, to be allocated in the next auction.

## Triggering another auction

The Diego Auction process repeats to adapt a TAS for VMs deployment to its changing workload. For example, the BBS initiates a new auction when it detects that the actual number of running instances of LRPs does not match the number desired. Diego's BBS component monitors the number of instances of each LRP that are currently running. The BBS component periodically compares this number with the desired number of LRP instances, as configured by the user. If the actual number falls short of what is desired, the BBS triggers a new auction. In the case of a surplus of app instances, the BBS stops the extra instances and initiates another auction.

Cloud Controller also starts an auction whenever a Diego Cell fails. After any auction, if a Diego Cell responds to its work request with a message that it cannot perform the work after all, the Auctioneer carries the unallocated work over into the next batch. But if the Diego Cell fails to respond entirely, for example if its connection times out, the unresponsive Diego Cell might still be running its' work. In this case, the Auctioneer does not automatically carry the Diego Cell's work over to the next batch. Instead, the Auctioneer defers to the BBS to continue monitoring the states of the Diego Cells, and to reassign unassigned work later if needed.

## High Availability in TAS for VMs

This topic tells you about the components used to ensure high availability in VMware Tanzu Application Service for VMs (TAS for VMs), vertical and horizontal scaling, and the infrastructure required to support scaling component VMs for high availability.

A system with high availability provides higher than typical uptime through redundancy of apps and component VMs. You can create the redundancy required for high availability in several ways, such as running VMs in multiple availability zones and using external blob storage solutions.

This topic provides you guidance on configuring your TAS for VMs deployment for high availability.

## Components of high availability deployments

You can use availability zones, external load balancers, and external blob storage to ensure high availability for your deployment.

### Availability zones

Availability Zones (AZs) are locations where public cloud services offer data centers.

You can assign and scale components in multiple AZs to help maintain high availability through redundancy. To configure sufficient redundancy, deploy TAS for VMs across three or more AZs and assign multiple component instances to different AZs.

Always use an odd number of AZs. This ensures that your deployment remains available as long as greater than half of the AZs are available.

For example, a deployment with three AZs stays available when one AZ is unavailable. A deployment with five AZs stays available when two AZs are unavailable.

### External load balancers

External load balancers distribute traffic coming from the internet to your internal network.

To ensure high availability for production environments, use a highly available customer provided external load balancing solution that does the following:

- Provides load balancing to each of the TAS for VMs router IP addresses.
- Supports SSL termination with wildcard DNS location.
- Adds appropriate `x-forwarded-for` and `x-forwarded-proto` HTTP headers to incoming requests.
- (Optional) Supports WebSockets.

For more information, see [Using your own load balancer](#).

## External blob storage

Blobs are large binary files, such as PDFs or images. To store blobs for high availability, use external storage such as Amazon S3 or an S3-compatible service.

You can also store blobs internally using WebDAV or NFS. These components run as single instances and you cannot scale them. For these deployments, use the high availability features of your IaaS to immediately recover your WebDAV or NFS server VM if it fails.

If you need assistance, contact [Support](#).

The singleton compilation components do not affect platform availability.

## Scaling platform capacity

You can scale platform capacity in the following ways:

- **Vertical scaling:** Add memory and disk to each VM.
- **Horizontal scaling:** Add more VMs that run instances of TAS for VMs components.

The type of apps you host on TAS for VMs determines whether you scale vertically or horizontally.

For more information about scaling apps and maintaining app uptime, see [Scaling an app using cf scale](#) and [Using Blue-Green Deployment to Reduce Downtime and Risk](#)

### Scaling vertically

Scaling vertically means adding memory and disk to your component VMs.

To scale vertically, allocate and maintain the following:

- Free space on host Diego Cell VMs so that apps expected to deploy can successfully be staged and run.
- Disk space and memory in your deployment so that if one host VM is down, all instances of apps can be placed on the remaining host VMs.
- Free space to handle one AZ going down if deploying in multiple AZs.

### Scaling horizontally

Scaling horizontally means increasing the number of instances of VMs that run a functional component of a system.

You can horizontally scale most TAS for VMs component VMs to multiple instances for high availability.

You must also distribute the instances of components across different AZs to minimize downtime during ongoing operation, product updates, and platform upgrades. For more information about using AZs, see [Availability Zones](#).

## Recommended instance counts for high availability

For more information regarding rolling app deployments, see [Scaling TAS for VMs](#).

The following table provides the instance counts that VMware recommends for a high-availability deployment and the minimum instances for a functional deployment:

VMware Tanzu Application Service for VMs Job	Recommended Instance Number for HA	Minimum Instance Number	Notes
Diego Cell	$\geq 3$	1	The optimal balance between CPU and memory sizing and instance count depends on the performance characteristics of the apps that run on Diego Cells. Scaling vertically with larger Diego Cells makes for larger points of failure, and more apps go down when a Diego Cell fails. On the other hand, scaling horizontally decreases the speed at which the system re-balances apps. Re-balancing 100 Diego Cells takes longer and demands more processing overhead than re-balancing 20 Diego Cells.
Diego Brain	$\geq 2$	1	For high availability, use at least one per AZ, or at least two if only one AZ.
Diego BBS	$\geq 2$	1	For high availability in a multi-AZ deployment, use at least one instance per AZ. Scale Diego BBS to at least two instances for high availability in a single-AZ deployment.
MySQL Server	3	1	If you use an external database in your deployment, you can set the MySQL Server instance count to 0. To scale down an internal MySQL cluster, see <a href="#">Scaling Down Your MySQL Cluster</a> in <a href="#">Scaling Internal MySQL</a> .
MySQL Proxy	2	1	If you use an external database in your deployment, then you can set the MySQL Proxy instance count to 0.
NATS	$\geq 2$	1	In a high-availability deployment, you might run a single NATS instance if your deployment lacks the resources to deploy two stable NATS servers. Components using NATS are resilient to message failures and the BOSH Resurrector recovers the NATS VM quickly if it becomes non-responsive.
Cloud Controller	$\geq 2$	1	Scale the Cloud Controller to accommodate the number of requests to the API and the number of apps in the system.
Clock Global	$\geq 2$	1	For a high-availability deployment, scale the Clock Global job to a value greater than 1 or to the number of AZs you have.
Router	$\geq 2$	1	Scale the Gorouter to accommodate the number of incoming requests. Additional instances increase available bandwidth. In general, this load is much less than the load on Diego Cells.
UAA	$\geq 2$	1	
Doppler Server	$\geq 2$	1	Deploying additional Doppler servers splits traffic across them. For a high-availability deployment, VMware recommends at least two per AZ.

VMware Tanzu Application Service for VMs Job	Recommended Instance Number for HA	Minimum Instance Number	Notes
Loggregator TrafficController	≥ 2	1	Deploying additional Loggregator TrafficController instances allows you to direct traffic to them in a round-robin manner. For a high-availability deployment, VMware recommends at least two per AZ.
Log Cache	≥ 3	1	Deploying additional Log Cache instances increases the total storage, sharding data by app ID. If app logs and metrics are sharded to an unavailable instance, they are unavailable when the designated instance is unavailable regardless of the number of instances or AZs. Data is not re-balanced unless you increase or decrease the number of desired instances in Operations Manager and apply changes.
CredHub	≥ 3	2	CredHub is a scalable component. For high availability, use at least one instance per AZ, or at least three instances if only one AZ is present.

## Infrastructure for component scaling

The ability to scale component VMs is important for high availability. To scale component VMs, you must make sure that the surrounding infrastructure of your deployment supports VM scaling.

Learn about the infrastructure required to support scaling component VMs for high availability.

## BOSH Resurrector

The BOSH Resurrector increases VMware Tanzu Application Service for VMs (TAS for VMs) availability in the following ways:

- Reacts to hardware failure and network disruptions by recreating VMs on active, stable hosts
- Detects operating system failures by continuously monitoring VMs and recreating them as required
- Continuously monitors the BOSH Agent running on each VM and recreates the VMs as required

The BOSH Resurrector continuously monitors the status of all VMs in a TAS for VMs deployment. The Resurrector also monitors the BOSH Agent on each VM. If either the VM or the BOSH Agent fail, the Resurrector recreates the VM on another active host. To enable the BOSH Resurrector, see the [Enable BOSH Resurrector](#) section of the *Using the BOSH Resurrector* topic.

## Resource pools

Each IaaS has different ways of limiting resource consumption for scaling VMs. Consult with your IaaS administrator to ensure additional VMs and related resources, like IPs and storage, are available to scale.

For more information about configuring your resource pools according to the requirements of your deployment, see the [Tanzu Operations Manager configuration topic for your IaaS](#).

For information about configuring resource pools for Amazon Web Services, see [Amazon EC2 FAQs](#) in the Amazon documentation.

For information about configuring resource pools for OpenStack, see [Manage projects and users](#) in the OpenStack documentation.

For information about configuring resource pools for vSphere, see the [Resource Config Pane](#) section of the *Configuring BOSH Director on vSphere* topic.

## Databases

For database services deployed outside TAS for VMs, use the high availability features included with your infrastructure. Also, configure backup and restore where possible. For more information about scaling internal database components, see [Scaling TAS for VMs](#).

Data services might have single points of failure depending on their configuration.

If you need assistance, contact [Support](#).

## How TAS for VMs Maintains High Availability

VMware Tanzu Application Service for VMs (TAS for VMs) deployments make up several layers of high availability to keep your apps running during system failure. These layers include AZs, app health management, process monitoring, and VM resurrection.

## Availability zones

Operations Manager supports deploying apps instances across multiple AZs. This level of high availability requires that you define AZs in your IaaS. Operations Manager balances the apps you deploy across the AZs you defined. If an AZ goes down, you still have app instances running in another.

You can configure your deployment so that Diego Cells are created across these AZs in the **Assign AZs and Networks** pane of the TAS for VMs tile.

## Health management for app instances

If you lose app instances for any reason, such as a bug in the app or an AZ going down, Operations Manager restarts new instances to maintain capacity. Under Diego architecture, the nsync, BBS, and Cell Rep components track the number of instances of each app that are running across all of the Diego cells. When these components detect a discrepancy between the actual state of the app instances in the cloud and the desired state as known by the Cloud Controller, they advise the Cloud Controller of the difference and the Cloud Controller initiates the deployment of new app instances.

For more information about the nsync, BBS, and Cell Rep components, see the [nsync, BBS, and Cell Rep](#) section of the *TAS for VMs Components* topic.

## Process monitoring

Operations Manager uses a BOSH agent, monit, to monitor the processes on the component VMs that work together to keep your apps running, such as nsync, BBS, and Cell Rep. If monit detects a failure, it restarts the process and notifies the BOSH agent on the VM. The BOSH agent notifies the BOSH Health Monitor, which starts the responders through plug-ins. For example, email notifications or paging.

## Resurrector VMs

BOSH detects if a VM is present by listening for heartbeat messages that are sent from the BOSH agent every 60 seconds. The BOSH Health Monitor listens for those heartbeats. When the Health Monitor finds that a VM is not responding, it passes an alert to the Resurrector component. If the Resurrector is enabled, it sends the IaaS a request to create a new VM instance to replace the one that failed.

To enable the Resurrector, see the following pages for your particular IaaS: [AWS](#), [Azure](#), [GCP](#), [OpenStack](#), or [vSphere](#).

## TAS for VMs Security

This topic provides you with an overview of VMware Tanzu Application Service for VMs (TAS for VMs) security. For an overview of container security, see [Container Security](#).

TAS for VMs implements the following measures to mitigate against security threats:

- Minimizes network surface area.
- Isolates customer apps and data in containers.
- Encrypts connections.
- Uses role-based access controls, applying and enforcing roles and permissions to ensure that users can only view and affect the spaces for which they have been granted access.
- Ensures security of app bits in a multi-tenant environment.
- Prevents possible denial of service attacks through resource starvation.

## System boundaries and access

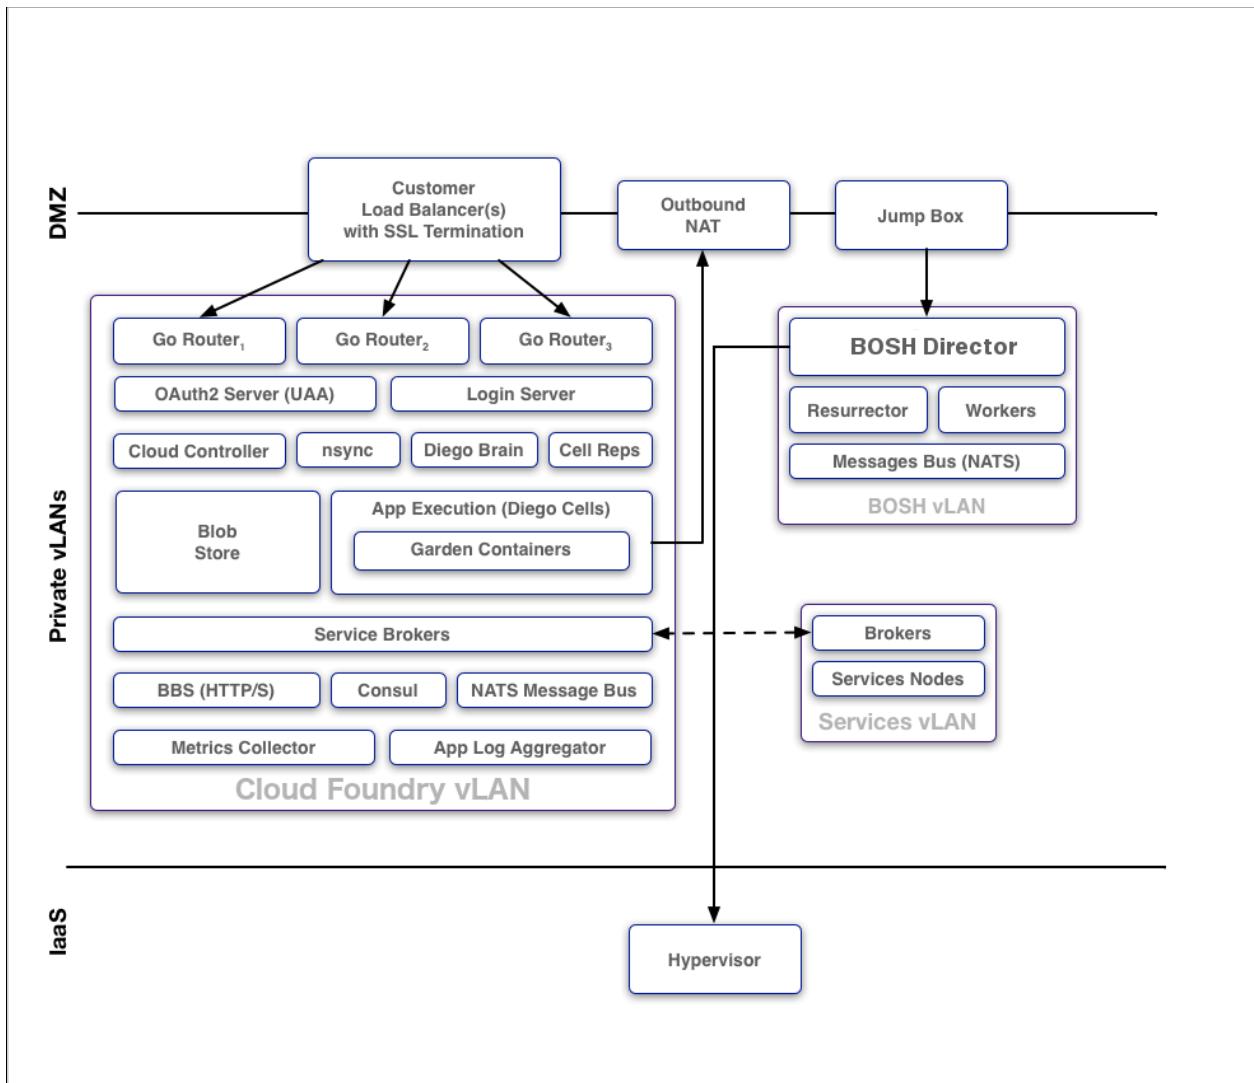

In a typical deployment of TAS for VMs, the components run on virtual machines (VMs) that exist within a VLAN.

In this configuration, the only access points visible on a public network are a load balancer that maps to one or more TAS for VMs routers and, optionally, a NAT VM and a jumpbox. Because of the limited number of contact points with the public internet, the surface area for possible security vulnerabilities is minimized.

As the following diagram shows the architecture of a typical deployment of TAS for VMs:

VMware recommends that you also install a NAT VM for outbound requests and a jumpbox to access the BOSH Director, though these access points are optional depending on your network configuration.

The diagram shows the following components:

- DMZ
  - Customer Load Balancers with SSL Termination
  - Outbound NAT
  - Jumpbox
- Private vLANs
  - Cloud Foundry vLAN
    - Three Go Routers
    - OAuth2 Server (UAA)
    - Login Server
    - Cloud Controller
    - nsync
    - Diego Brain
    - Cell Reps
    - Blob Store
  - BOSH vLAN
    - BOSH Director
    - Resurrector
    - Workers
    - Messages Bus (NATS)

- App Execution (Diego Cells) with Garden Containers
- Service Brokers
- BBS (HTTP/S)
- Consul
- NATS Message Bus
- Metrics Collector
- App Log Aggregator
- BOSH vLAN
  - BOSH Director
  - Resurrector
  - Workers -Message Bus (NATS)
- Services vLAN
  - Brokers
  - Services Nodes
- IaaS
  - Hypervisor

The preceding diagram shows the following communications:

- Customer Load Balancers send communication to the three Go Routers.
- Outbound NAT communicates with Hypervisor.
- BOSH Director communicates with the App Execution (Diego Cells).
- Service Brokers in Cloud Foundry vLAN communicates with Brokers in Services vLAN.

## Protocols

All traffic from the public internet to the Cloud Controller and UAA happens over HTTPS. Inside the boundary of the system, components communicate over a publish-subscribe (pub-sub) message bus NATS, HTTP, and SSL/TLS.

## BOSH

Operators deploy TAS for VMs with BOSH. The BOSH Director is the core orchestrating component in BOSH: it controls VM creation and deployment, as well as other software and service lifecycle events. You use HTTPS to ensure secure communication to the BOSH Director.

VMware recommends that you deploy the BOSH Director on a subnet that is not publicly accessible, and access the BOSH Director from a jumpbox on the subnet or through VPN.

BOSH includes the following capability for security:

- Communicates with the VMs it runs through NATS. Because NATS cannot be accessed from outside TAS for VMs, this ensures that published messages can only originate from a component within your deployment.

- Provides an audit trail through the `bosh tasks --all` and `bosh tasks --recent=VALUE` commands. `bosh tasks --all` returns a table that shows all BOSH actions taken by an operator or other running processes. `bosh tasks --recent=VALUE` returns a table of recent tasks, with `VALUE` being the number of recent tasks you want to view.
- Allows you to set up individual login accounts for each operator. BOSH operators have root access.

BOSH does not encrypt data stored on BOSH VMs. Your IaaS might encrypt this data.

## Isolation segments

Isolation segments provide dedicated pools of resources to which apps can be deployed to isolate workloads. Using isolation segments separates app resources as completely as if they were in different TAS for VMs deployments but avoids redundant management components and unneeded network complexity.

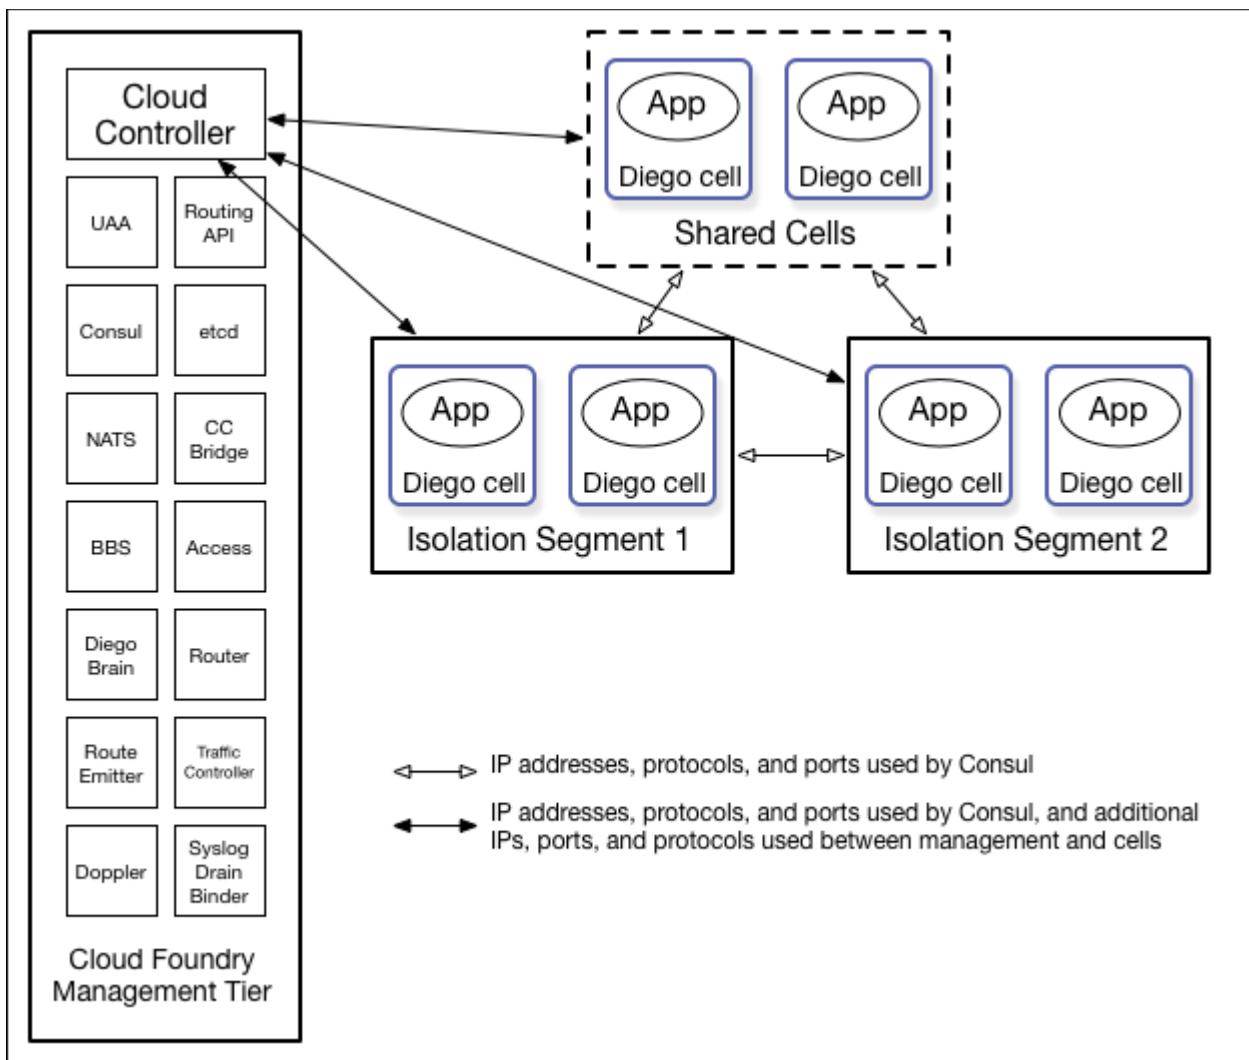

You can designate isolation segments for exclusive use by orgs and spaces within TAS for VMs. This guarantees that apps within the org or space use resources that are not also used by other orgs or spaces. For more information, see [Orgs, Spaces, Roles, and Permissions](#).

Customers can use isolation segments for different reasons, including:

- To follow regulatory restrictions that require separation between different types of apps. For example, a health care company might not be able to host medical records and billing systems on the same machines.
- To dedicate specific hardware to different isolation segments. For example, to ensure that high-priority apps run on a cluster of high-performance hosts.
- To separate data on multiple clients, to strengthen a security story, or offer different hosting tiers.

In TAS for VMs, the Cloud Controller database (CCDB) identifies isolation segments by name and GUID, for example `30dd879c-ee2f-11db-8314-0800200c9a66`. The isolation segment object has no internal structure beyond these two properties at the TAS for VMs level, but BOSH associates the name of the isolation segment with Diego Cells, through their `placement_tag` property.

This diagram shows how isolation segments keep apps running on different pools of Diego Cells, and how the Diego Cells communicate with each other and with the management components:

For more information about how to create and manage isolation segments in an Tanzu Operations Manager deployment, see [Installing Isolation Segment](#) and [Managing Isolation Segments](#).

For API commands related to isolation segments, see [Isolation Segments](#) in the Cloud Controller API (CAPI) Reference.

## Authentication and authorization

User Account and Authentication (UAA) is the central identity management service for TAS for VMs and its various components.

UAA acts as an OAuth2 Authorization Server and issues access tokens for apps that request platform resources. The tokens are based on the [JSON Web Token](#) and are digitally signed by UAA.

Operators can configure the identity store in UAA. If users register an account with the TAS for VMs platform, UAA acts as the user store and stores user passwords in the UAA database using [bcrypt](#). UAA also supports connecting to external user stores through LDAP and SAML. Once an operator has configured the external user store, such as a corporate Microsoft Active Directory, users can use their LDAP credentials to gain access to the TAS for VMs platform instead of registering a separate account. Alternatively, operators can use SAML to connect to an external user store and enable single sign-on for users into the TAS for VMs platform.

Standard TAS for VMs deployments based on [cf-deployment](#) provide a UAA client `cf` that can be used to create OAuth 2 tokens using the Password Grant Flow for TAS for VMs users that are needed to access the CF API. This UAA client is also used by the CF CLI. The UAA client `cf` doesn't require a `client_secret`.

## Managing user access with Role-Based Access Control

Apps that users deploy to TAS for VMs exist within a space. Spaces exist within orgs. To view and access an org or a space, a user must be a member of it. TAS for VMs uses role-based access control (RBAC), with each role granted permissions to either an org or a specified space. For more information about roles and permissions, see [Orgs, Spaces, Roles, and Permissions](#).

For more information, see [Getting started with Apps Manager](#) and [Managing User Roles using Apps Manager](#).

## Security for service broker integration

The Cloud Controller authenticates every request with the Service Broker API using HTTP or HTTPS, depending on which protocol that you specify during broker registration. The Cloud Controller rejects any broker registration that does not contain a username and password.

Service instances bound to an app contain credential data. Users specify the binding credentials for user-provided service instances, while third-party brokers specify the binding credentials for managed service instances. The VCAP\_SERVICES environment variable contains credential information for any service bound to an app. TAS for VMs constructs this value from encrypted data that it stores in the CCDB. For more information about user-provided service instances, see [User-Provided Service Instances](#).

The selected third-party broker controls how securely to communicate managed service credentials.

A third-party broker might offer a dashboard client in its catalog. Dashboard clients require a text string defined as a `client_secret`. TAS for VMs does not store this secret in the CCDB. Instead, TAS for VMs passes the secret to the UAA component for verification using HTTP or HTTPS.

## Managing software vulnerabilities

TAS for VMs manages software vulnerability using releases and BOSH stemcells. New TAS for VMs releases are created with updates to address code issues, while new stemcells are created with patches for the latest security fixes to address any underlying operating system issues.

## Ensuring security for app artifacts

TAS for VMs secures both the code and the configuration of an app using the following functions:

- App developers push their code using the TAS for VMs API. TAS for VMs secures each call to the TAS for VMs API using the [UAA](#) and SSL.
- The Cloud Controller uses [RBAC](#) to ensure that only authorized users can access a particular app.
- The Cloud Controller stores the configuration for an app in an encrypted database table. This configuration data includes user-specified environment variables and service credentials for any services bound to the app.

- TAS for VMs runs the app inside a secure container. For more information, see [Container Security](#).
- TAS for VMs operators can configure network traffic rules to control inbound communication to and outbound communication from an app. For more information, see the [Network Traffic Rules](#) section of the *Container Security* topic.

## Security event logging and auditing

For operators, TAS for VMs provides an audit trail through the `bosh tasks` command. This command shows all actions that an operator has taken with the platform. Additionally, operators can redirect TAS for VMs component logs to a standard syslog server using the `syslog_daemon_config` property in the `metron_agent` job of `cf-release`.

For users, TAS for VMs records an audit trail of all relevant API invocations of an app. The Cloud Foundry Command Line Interface (cf CLI) command `cf events` returns this information.

## Recommendations for running a secure deployment

To help run a secure deployment, VMware recommends:

- Configure UAA clients and users using a BOSH manifest. Limit and manage these clients and users as you would any other kind of privileged account.
- Deploy within a VLAN that limits network traffic to individual VMs. This reduces the possibility of unauthorized access to the VMs within your BOSH-managed cloud.
- Enable HTTPS for apps and SSL database connections to protect sensitive data transmitted to and from apps.
- Ensure that the jumpbox is secure, along with the load balancer and NAT VM.
- Encrypt stored files and data within databases to meet your data security requirements. Deploy using industry standard encryption and the best practices for your language or framework.
- Prohibit promiscuous network interfaces on the trusted network.
- Review and monitor data sharing and security practices with third party services that you use to provide additional function to your app.
- Store SSH keys securely to prevent disclosure, and promptly replace lost or compromised keys.
- Use TAS for VMs's RBAC model to restrict your users' access to only what is necessary to complete their tasks.
- Use a strong passphrase for both your TAS for VMs user account and SSH keys.

Use the [IPsec for VMware Tanzu](#) to encrypt IP data traffic within your deployment.

## Compliance

For information about compliance in TAS for VMs, see the following topics:

- [NIST Controls and VMware Tanzu Application Service for VMs](#): Provides a dedicated site that assesses TAS for VMs against NIST SP 800-53(r4) Controls.

- [General Data Protection Regulation](#): Provides an overview of the General Data Protection Regulation (GDPR) and where TAS for VMs might store personal data.

## Security for apps and services

This section links to topics that describe how TAS for VMs and TAS for VMs users manage security for apps and service instances.

- [App Security Groups](#): Describes how App Security Groups (ASGs) work and how to manage them in TAS for VMs.
- [Configuring SSH Access for TAS for VMs](#): Explains how to configure TAS for VMs to allow SSH access to app instances for debugging.
- [Restricting App Access to Internal TAS for VMs Components](#): Details how to create ASGs, rules that allow internal outgoing communications from all apps in TAS for VMs, or the apps running in the same space.
- [Configuring App Security Groups for Email Notifications](#): Describes how to define an ASG to enable app-generated notifications.
- [Trusted System Certificates](#): Explains where apps can find trusted system certificates.
- [Managing Access to Service Plans](#): Describes how to activate or deactivate access to service plans for a subset of users.
- [Delivering Service Credentials to an App](#): Describes how to bind apps to service instances, which generate the credentials that enable the apps to use the service.
- [Managing Service Keys](#): Explains how to create and manage service keys that allow apps to use service instances.

## General Data Protection Regulation and TAS for VMs

Learn about the General Data Protection Regulation (GDPR) and where VMware Tanzu Application Service for VMs (TAS for VMs) might store personal data.

GDPR came into effect on May 25, 2018 and affects any company processing the data of EU citizens or residents, even if the company is not EU-based. The GDPR sets forth how companies can handle privacy issues, securely store data, and respond to security breaches.

## Process personal data

The GDPR grants data subjects certain rights, such as the right to obtain a copy of their personal data, object to the processing of personal data, and the right to have their personal data erased. Organizations subject to GDPR need to ensure that they can address and respond to requests by data subjects if they are processing their personal data.

Article 4, Section 1 of the GDPR defines personal data as follows:

*'personal data' is any information relating to an identified or identifiable natural person ('data subject'); an identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more*

*factors specific to the physical, physiological, genetic, mental, economic, cultural or social identity of that natural person;*

For more information, see the [GDPR text](#).

Personal data can be collected, stored, and processed in a TAS for VMs deployment. VMware has performed a review of TAS for VMs components and determined that personal data might reside in the areas discussed in the following sections.

## Where personal data might reside

The following sections explain how different TAS for VMs components collect personal data.

### User Account and Authentication (UAA)

UAA is an open-source Cloud Foundry component that provides identity management features and identity-based security for apps and APIs. For more information, see [User Account and Authentication](#).

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?
<b>Business Initiation</b>	User registers	<ul style="list-style-type: none"> <li>• Username</li> <li>• Email address</li> <li>• First name (optional )</li> <li>• Last name (optional )</li> <li>• User ID (UAA GUID, generate d)</li> </ul>	User registration submission	UAA DB	Stored in UAA DB	<ul style="list-style-type: none"> <li>• End user</li> <li>• UAA administrators</li> </ul>

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?
	Just-in-time provisioning: create user on user login	<ul style="list-style-type: none"> <li>• Username</li> <li>• Email address</li> <li>• First name (optional)</li> <li>• Last name (optional)</li> <li>• User ID (UAA GUID, generated)</li> <li>• Additional attributes as defined by the organization</li> </ul>	User login	UAA DB	Stored in UAA DB	UAA administrators

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?
	Admin user makes a creation API call	<ul style="list-style-type: none"> <li>• Username</li> <li>• Email address</li> <li>• First name (optional)</li> <li>• Last name (optional)</li> <li>• User ID (UAA GUID, generated)</li> <li>• Additional attributes as defined by the organization</li> </ul>	Admin API call	UAA DB	Stored in UAA DB	UAA administrators
<b>Business Execution</b>	User self-updates profile	<ul style="list-style-type: none"> <li>• Email address</li> <li>• First name (optional)</li> <li>• Last name (optional)</li> </ul>	User registration submission	UAA DB	Stored in UAA DB	<ul style="list-style-type: none"> <li>• End user</li> <li>• UAA administrators</li> </ul>

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?
	Just-in-time provisioning: user update	<ul style="list-style-type: none"> <li>Email address</li> <li>First name (optional)</li> <li>Last Name (optional)</li> <li>Additional attributes as defined by the organization</li> </ul>	User login	UAA DB	Stored in UAA DB	UAA administrators
	User logs in	<ul style="list-style-type: none"> <li>Current account cookie (generated)</li> <li>Saved account cookie (generated)</li> </ul>	User login	User browser	By UAA	<ul style="list-style-type: none"> <li>End user</li> <li>UAA login page</li> </ul>

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?	How long is it kept?
	Audit what changes a user makes	<ul style="list-style-type: none"> <li>IP address</li> <li>Email address</li> <li>User ID</li> <li>User name</li> </ul>	<ul style="list-style-type: none"> <li>On each request</li> </ul>	<ul style="list-style-type: none"> <li>Local VM: CEF logs</li> <li>Log aggregator or used by Open ratio ns</li> <li>Manager operator</li> <li>Administrator</li> </ul>	n/a	<ul style="list-style-type: none"> <li>Operations Manager operator</li> </ul>	<ul style="list-style-type: none"> <li>Local VM: 4 week maximum by default</li> <li>Log aggregator</li> <li>or as configured by default</li> <li>Operations Manager operator</li> </ul>
	Audit what user created a resource	<ul style="list-style-type: none"> <li>Name</li> <li>User ID</li> <li>Email address</li> </ul>	<ul style="list-style-type: none"> <li>When API resources are created</li> </ul>	<ul style="list-style-type: none"> <li>As part of the resource row in Cloud Controller DB</li> </ul>	n/a	<ul style="list-style-type: none"> <li>Operations Manager operator</li> </ul>	<ul style="list-style-type: none"> <li>As long as the resource exists</li> </ul>
						<ul style="list-style-type: none"> <li>Users that can view the resource</li> </ul>	

## Routing

By default, the Gorouter logs include the `X-Forwarded-For` header, which might include the originating client IP. Under GDPR, client IP addresses can be considered personal data.

### Deactivate client IP logging

In TAS for VMs v2.0 and later and Elastic Runtime v1.12, you can deactivate logging of client IP addresses in the Gorouter.

To deactivate logging of client IP addresses:

1. Go to the Tanzu Operations Manager Installation Dashboard and click the **TAS for VMs or Elastic Runtime** tile.
2. Click **Networking**.
3. In **Client IP Logging**::
  - If the source IP address exposed by your load balancer is its own IP address, select **Do not log X-Forwarded-For header**.
  - If the source IP address exposed by your load balancer belongs to the downstream client, select **Do not log source IP or X-Forwarded-For header**.
4. Click **Save**.
5. Return to the Tanzu Operations Manager Installation Dashboard, click **Review Pending Changes**, and click **Apply Changes** to redeploy.

## Diego

Diego is the container management system for TAS for VMs. For more information, see [Diego Components and Architecture](#).

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?	How can I delete it?
<b>Business Execution</b>	Executing apps and tasks	No personal data is collected explicitly, but personal data might be encoded in app file contents or runtime metadata such as Diego environment variables or start commands.	Runtime metadata is collected when Cloud Controller submits work specification to the Diego BBS API. File contents are collected when Diego schedules an app or a task on a Diego Cell.	Runtime metadata is stored in the Diego BBS DB. App file contents are cached on Diego Cells.	Runtime metadata is used to start processes inside app instance containers and to configure their environment. App file contents are presented as part of the app instance container filesystem.	Platform operators and other developers with access to the Cloud Controller space containing that app can view the data.	<ul style="list-style-type: none"> <li>To delete the runtime metadata stored in the Diego BBS DB, stop the app or cancel the task that includes that data.</li> <li>To delete the app file contents stored in the running app and task containers, stop the app or cancel the task to destroy the containers. To get rid of the app file contents stored in the download</li> </ul>

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?	How can I delete it?
							cache on the Diego Cells, recreate the Diego Cell VMs.

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?	How can I delete it?
Reports/Logs	SSH proxy logs TAS for VMs user access.	UAA user name and ID	When the user authenticates for SSH access to an app.	The data is stored in a log file collocated with the SSH proxy instance handling the authentication request. This log file can also have its contents forwarded to a remote syslog destination.	No processing of the local log file is done automatically. If the log file contents are forwarded to a log aggregation service, they might be parsed and processed arbitrarily.	Only platform operators have access to the local log file. Platform operators or auditors have access to these log contents in a downstream log aggregation service.	<p>To delete the log lines containing the user ID:</p> <ol style="list-style-type: none"> <li>1. Run <code>bosh recreate</code> on the VMs hosting the SSH proxy processes to remove all the logs on ephemeral disk.</li> <li>2. <code>bosh ssh</code> into the VMs hosting the SSH proxy processes and remove specific log lines containing user IDs.</li> <li>3. Scrub corresponding log lines from any log aggregation service.</li> </ol>

## Notifications Service

The Notifications Service allows you to configure components of TAS for VMs to send emails to end users. For more information, see [Getting Started with the Notifications Service](#).

GDPR	Workflow	What personal data is collected?	When is it collected?	Where is it stored?	How is it processed?	Who has access to it?
<b>Business Executive</b>	Sending email to UAA users	User ID	First email sent	The <code>receipts</code> table in the Notifications database	Stored in the Notifications database	Notifications operator making a database query
	UAA user unsubscribes globally	User ID	When the UAA user unsubscribes	The <code>global_unsubscribes</code> table in the Notifications database	Stored in the Notifications database	Notifications operator making a database query
	UAA user unsubscribes from a specific kind of email	User ID	When the UAA user unsubscribes	The <code>unsubscribes</code> table in the Notifications database	Stored in the Notifications database	Notifications operator making a database query
	UAA user unsubscribes from a campaign in the v2 API	User ID	When the UAA user unsubscribes	The <code>unsubscribes</code> table in the Notifications database	Stored in the Notifications database	Notifications operator making a database query
<b>Reports/Logs</b>	UAA user unsubscribes	User email address	When the UAA user unsubscribes	Log output	Loggregator	Loggregator Firehose users

## TAS for VMs

The VMware Tanzu Application Service for VMs runtime is available in two forms, both available to download from the [VMware Tanzu Application Service for VMs](#) page on Broadcom Support:

- TAS for VMs
- Small Footprint TAS for VMs

For more information about the difference, see the following sections.

## When should you use Small Footprint TAS for VMs?

Use Small Footprint TAS for VMs for smaller foundations on which you intend to host 2500 or fewer application instances, as described in [Limitations](#). If you want to use Small Footprint TAS for VMs in a production environment, ensure the limitations described are not an issue in your use case.

Small Footprint TAS for VMs is compatible with VMware Tanzu Operations Manager (Tanzu Operations Manager) service tiles.

Small Footprint TAS for VMs is also ideal for the following use cases:

- **Proof-of-concept installations:** Deploy Tanzu Operations Manager quickly and with a small footprint for evaluation or testing purposes.
- **Sandbox installations:** Use Small Footprint TAS for VMs as an Tanzu Operations Manager operator sandbox for tasks such as testing compatibility.
- **Service tile R&D:** Test a service tile against Small Footprint TAS for VMs instead of a standard TAS for VMs deployment to increase efficiency and reduce cost.

## Small Footprint TAS for VMs Limitations

Small Footprint TAS for VMs has the following limitations:

- **Number of application instances:** The tile is not designed to support large numbers of app instances. You cannot scale the number of Compute VMs beyond 10 instances in the [Resource Config](#) pane. Small Footprint TAS for VMs is designed to support 2500 or fewer apps.
- **Management plane availability during tile upgrades:** You might not be able to perform management plane operations like deploying new applications and accessing APIs for brief periods during tile upgrades. The management plane is located on the Control VM.
- **Application availability during tile upgrades:** If you require availability during tile upgrades, you must scale your Compute VMs to a highly available configuration. Ensure sufficient capacity exists to move app instances between Compute VM instances during the upgrade.

## TAS for VMs requirements

For information about resource requirements for TAS for VMs and Small Footprint TAS for VMs, see [TAS for VMs resource requirements](#).

## TAS for VMs Resource Requirements

The general requirements for deploying and managing an installation of Tanzu Operations Manager and VMware Tanzu Application Service for VMs (TAS for VMs) are:

- A wildcard DNS record that points to your Gorouter or load balancer. Also, you can use a service such as xip.io. For example, `203.0.113.0.xip.io`.
  - TAS for VMs gives each app its own hostname in your app domain.
  - With a wildcard DNS record, every hostname in your domain resolves to the IP address of your Gorouter or load balancer, and you do not have to configure an A record for each app hostname. For example, if you create a DNS record `*.example.com` pointing to your load balancer or Gorouter, every app deployed to the `example.com` domain resolves to the IP address of your Gorouter.
- At least one wildcard TLS certificate that matches the DNS record you set up, `*.example.com`.
- Sufficient IP allocation:
  - One static IP address for one of your Gorouters.
  - One static IP address for each job in the TAS for VMs tile. For a full list, see the **Resource Config** pane for each tile.
  - One static IP address for each of the following jobs:
    - Consul
    - NATS
    - File Storage
    - MySQL Proxy
    - MySQL Server
    - Backup Restore Node
    - Router
    - MySQL Monitor
    - Diego Brain
    - TCP Router
  - One IP for each VM instance created by the service.
  - An additional IP address for each compilation worker. The formula for total IPs needed is `IPs needed = static IPs + VM instances + compilation workers`.

VMware recommends that you allocate at least 36 dynamic IP addresses when installing TAS for VMs. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install TAS for VMs, and connect to services.

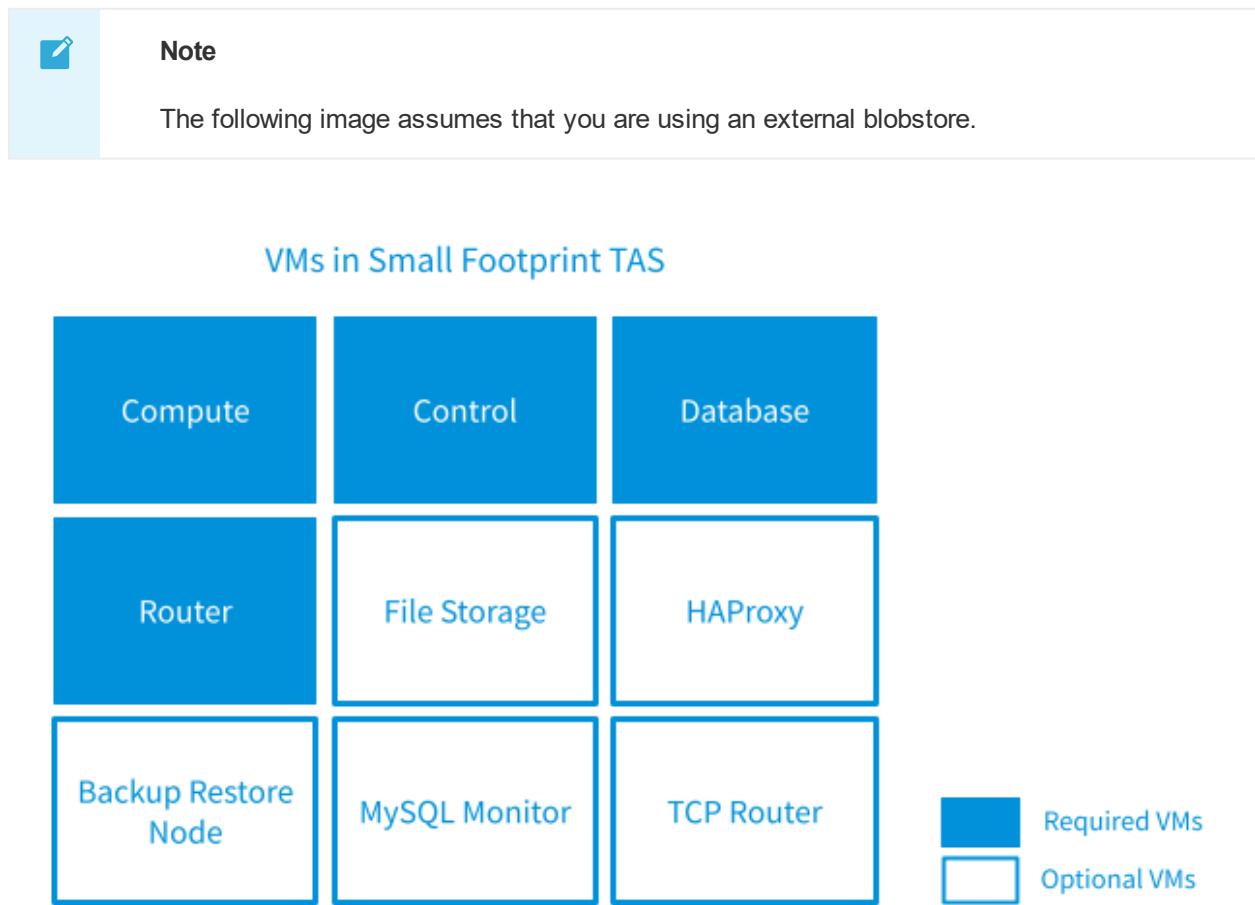

- One or more NTP servers if not already provided by your IaaS.
- (**Recommended**) A network without DHCP available for deploying the TAS for VMs VMs.

If you have DHCP, see [Troubleshooting Deployment Problems](#) in the Tanzu Operations Manager documentation for information about avoiding issues with your installation.

- **(Optional)** External storage. When you deploy TAS for VMs, you can select internal file storage or external file storage, either network-accessible or IaaS-provided, as an option in the TAS for VMs tile. VMware recommends using external storage whenever possible. For more information about how file storage location affects platform performance and stability during upgrades, see [Configure File Storage](#) in *Configuring TAS for VMs for Upgrades*.
- **(Optional)** External databases. When you install TAS for VMs, you can select internal or external databases for the BOSH Director and for TAS for VMs. VMware recommends using external databases in production deployments. An external database must be configured to use the UTC timezone.
- **(Optional)** External user stores. When you deploy TAS for VMs, you can select a SAML user store for Tanzu Operations Manager or a SAML or LDAP user store for TAS for VMs, to integrate existing user accounts.
- The most recent version of the [Cloud Foundry Command Line Interface](#) (cf CLI).

## Differences in Small Footprint TAS for VMs

You can deploy Small Footprint TAS for VMs with a minimum of four VMs, as shown in the following image.

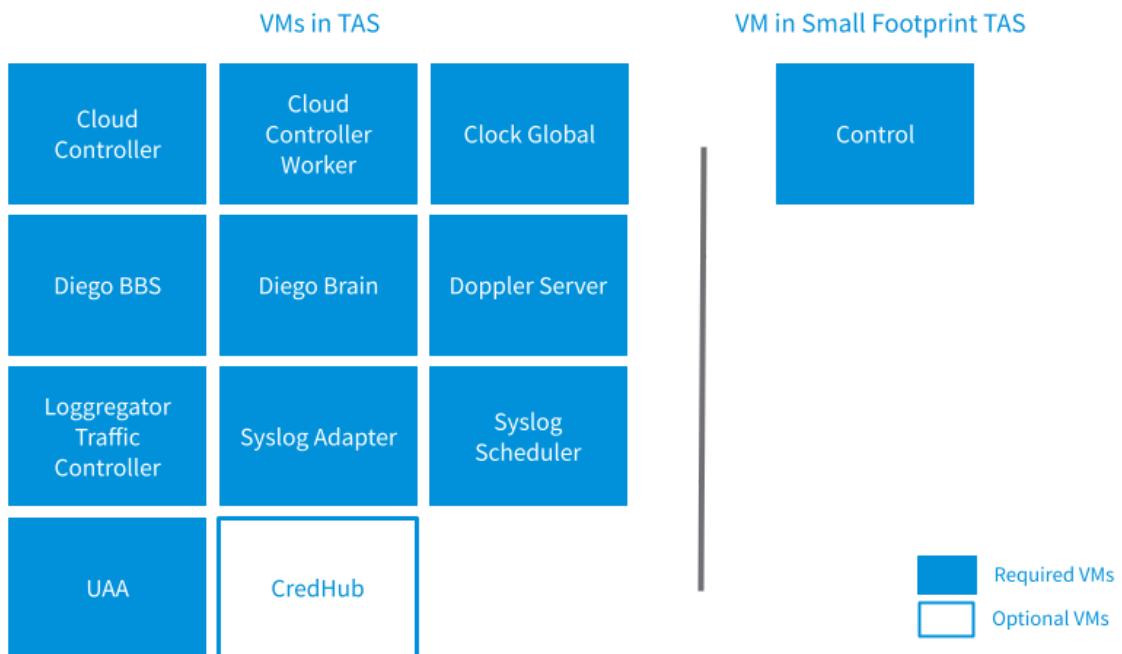

To reduce the number of VMs required for Small Footprint TAS for VMs, the Control and Database VMs include co-located jobs that run on a single VM in TAS for VMs. See the next sections for details.

For more information about the components mentioned on this page, see [TAS for VMs Components](#).

## Control VM

The Control VM includes the TAS for VMs jobs that handle management plane operations, app life cycles, logging, and user authorization and authentication. Additionally, all errands run on the Control VM, eliminating the need for a VM for each errand and significantly reducing the time it takes to run errands.

The following image shows all the jobs from TAS for VMs that are co-located on the Control VM in Small Footprint TAS for VMs. Small Footprint TAS for VMs co-locates 11 VMs onto 1 VM called Control. The 11 VMs are Cloud Controller, Cloud Controller Worker, Clock Global, Diego BBS, Diego Brain, Doppler Server, Loggregator Traffic Controller, Syslog Adapter, Syslog Scheduler, UAA, and optionally, CredHub.

## Database VM

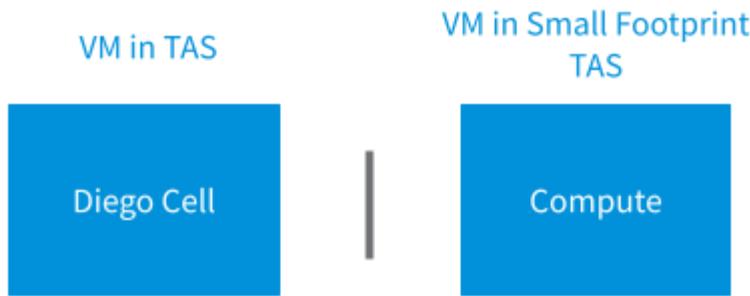

The Database VM includes the TAS for VMs jobs that handle internal storage and messaging.

The following image shows all the jobs from TAS for VMs that are co-located on the Database VM in Small Footprint TAS for VMs. Small Footprint TAS for VMs Condenses 3 VMs onto 1 VM called Database. The three TAS for VMs VMs are NATS, MySQL Proxy, and MySQL Server. The MySQL Proxy and MySQL Server are optional VMs.

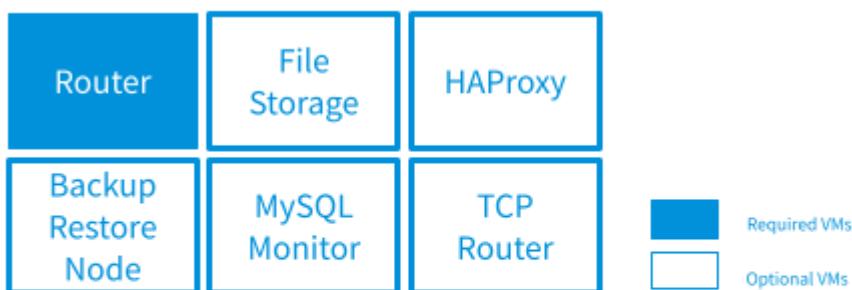

## Compute VM

The Compute VM is the same as the Diego Cell VM in TAS for VMs.

## Other VMs (unchanged)

For the other VMs, they perform the same functions in both versions of the TAS for VMs tile. The Router, File Storage, Backup Restore Node, MySQL Monitor, and TCP Router VMs are the same in both TAS for VMs and Small Footprint TAS for VMs.

## Instance number and scaling requirements

By default, TAS for VMs deploys the number of VM instances required to run a highly available configuration. If you are deploying a test or sandbox TAS for VMs that does not require HA, then you can scale down the number of instances in your deployment.

For information about the number of instances required to run a minimal, non-HA TAS for VMs deployment, see [Scaling TAS for VMs](#).

## Configuring TAS for VMs

In this section:

- [Prerequisites](#)
- [Add TAS for VMs to Tanzu Operations Manager](#)
- **Configure TAS features**
  - [Domains](#)
  - [Networking](#)
  - [App containers](#)

- App Developer Controls
  - Authentication and enterprise SSO
  - UAA
  - CredHub
  - Databases
  - File Storage
  - Cloud Controller
  - Smoke tests
  - Errands
  - Resources
  - Stemcell
  - Complete the TAS for VMs Installation
- **Configure optional features**
    - Internal MySQL
    - System logging
    - Custom branding and Apps Manager
    - Email notifications
    - App Autoscaler
    - Advanced features
    - Metric Registrar

## VMware Tanzu Application Service for VMs Overview

You can configure VMware Tanzu Application Service for VMs (TAS for VMs) as part of deploying Operations Manager.

## Prerequisites

Before you begin, you must:

- Ensure that you have successfully completed the steps to prepare your environment for Operations Manager and install and configure the BOSH Director. For more information, see the configuration topic for your IaaS in the [VMware Tanzu Operations Manager documentation](#).
- If you plan to install the Operations Manager IPsec add-on, you must do so before installing any other tiles. VMware recommends installing IPsec immediately after Tanzu Operations Manager and before installing the TAS for VMs Runtime tile. For more information, see [Installing IPsec for VMware Tanzu](#).

## Add TAS for VMs to Tanzu Operations Manager

Before you configure TAS for VMs, you must add the TAS for VMs tile to your Tanzu Operations Manager Installation Dashboard.

To add the TAS for VMs tile to your Tanzu Operations Manager Installation Dashboard:

1. If you have not already downloaded TAS for VMs, log in to [Broadcom Support](#) and click **VMware Tanzu Application Service for VMs**.
2. From the **Releases** drop-down menu, select the release to install and choose one of the following:
  1. Click **VMware Tanzu Application Service for VMs** to download the Pivotal Application Service `.pivotal` file.
  2. Click **Small Footprint TAS for VMs** to download the Small Footprint TAS for VMs `.pivotal` file.
3. Go to Tanzu Operations Manager Installation Dashboard.
4. Click **Import a Product** to add your tile to VMware Tanzu Operations Manager. For more information, see [Adding and Deleting Products](#).
5. Click the **VMware Tanzu Application Service for VMs** tile in the Installation Dashboard.

## Assign AZs and networks

For Azure environments, this configuration pane is **Assign Networks** and does not include AZ configuration.

In the **Assign AZ and Networks** pane, you assign jobs to your Availability Zones (AZs) and networks.

To configure the **Assign AZ and Networks** pane:

1. Select **Assign AZ and Networks**.
2. Under **Balance other jobs**, select all AZs. Tanzu Operations Manager balances instances of jobs with more than one instance across the AZs that you specify.  
For production deployments, VMware recommends at least three AZs for a highly available installation of TAS for VMs.
3. From the **Network** drop-down menu, select the network where you want to run TAS for VMs.
4. Click **Save**.

## Configure TAS features

In this section:

- [Domains](#)
- [Networking](#)
- [App containers](#)
- [App Developer Controls](#)
- [Authentication and enterprise SSO](#)
- [UAA](#)
- [CredHub](#)

- [Databases](#)
- [File Storage](#)
- [Cloud Controller](#)
- [Smoke tests](#)
- [Errands](#)
- [Resources](#)
- [Stemcell](#)
- [Complete the TAS for VMs Installation](#)

## Domains

In the **Domains** pane, you configure a wildcard DNS record for both the apps domain and system domain.

To configure the **Domains** pane:

1. Select **Domains**.
2. Enter the name of your system domain in the **System domain** field. The system domain defines your target when you push apps to TAS for VMs, such as your load balancer. TAS for VMs assigns system components such as UAA and Apps Manager to subdomains under this domain.
3. Enter the name of your apps domain in the **Apps domain** field. The apps domain is the default domain that apps use for their hostnames. TAS for VMs hosts each app at subdomains under this domain. You can use the Cloud Foundry Command Line Interface (cf CLI) to add or delete subdomains assigned to individual apps.
4. Click **Save**.

For additional guidance based on your installation method, see the table below:

Installation Method	Guidance
Manual	Enter the domains you created when preparing your environment for Operations Manager.
Terraform	Enter the values for <code>sys\_domain</code> and <code>apps\_domain</code> from the Terraform output.

VMware recommends that you use the same domain name but different subdomain names for your system and app domains. Doing so allows you to use a single wildcard certificate for the domain while preventing apps from creating routes that overlap with system routes.

## Networking

In the **Networking** pane, you configure security and routing services for your IaaS.

To configure the **Networking** pane:

## Gorouter IPs

For **Gorouter IPs**, see the guidance below:

- For **AWS**, **Azure**, and **GCP**, leave these fields blank. You do not need to configure these fields when deploying TAS for VMs on these infrastructures.
- For **OpenStack** and **vSphere**, use the table below to determine how to configure this field:

If you choose to assign specific IP addresses in the **Gorouter IPs** field, ensure that these IP addresses are in the subnet that you configured for TAS for VMs in Tanzu Operations Manager.

#### **Gorouter IPs field**

- Choose IP addresses from the subnet you configured in Tanzu Operations Manager.
- Enter these IP addresses in **Gorouter IPs**. You should specify more than one IP address for high availability. The IP addresses must be within your subnet CIDR block.
- Configure your load balancer to forward requests for the domains that you have configured for your deployment to these IP addresses.

## SSH proxy IPs and TCP router IPs

For **SSH Proxy IPs** and **TCP router IPs**, see the guidance below:

- For **AWS**, **Azure**, and **GCP**, leave these fields blank. You do not need to configure these fields when deploying TAS for VMs on these infrastructures.
- For **OpenStack** and **vSphere**:
  - (Optional) In **SSH Proxy IPs**, add the IP address for your Diego Brain, which accepts requests to SSH into app containers on port `2222`.
  - (Optional) In **TCP router IPs**, add the IP addresses you want to assign to the TCP routers. You configure TCP routing at the bottom of this pane.

If you configure mutual TLS app identity verification, app containers accept incoming communication only from the Gorouter. This deactivates TCP routing.

## Certificates and private keys for the Gorouter

Under **Certificates and private keys for the Gorouter**, you must provide at least one certificate and private key pair for the Gorouter. The Gorouter is configured to receive TLS communication by default. You can configure multiple certificates for the Gorouter.

When providing custom certificates, enter them in this order: `wildcard`, `Intermediate`, `CA`. For more information, see the [DigiCert documentation](#).

- To configure a certificate and private key for the Gorouter:
  - Click **Add**. The Gorouter uses the certificate you configure as the default certificate.
  - For **Name**, enter a human-readable name that describes the use of this certificate.

3. For **Certificate and private key**, choose one of the following options:
  - Enter a certificate signed by a Certificate Authority (CA).
  - Click **Generate RSA Certificate**. Clicking this link causes the Tanzu Operations Manager CA to automatically generate a certificate.

For the values to use, see [Providing a Certificate for your TLS termination point](#).

If you configured your Tanzu Operations Manager front end without a certificate, you can use this new certificate to finish configuring Tanzu Operations Manager. To configure your Tanzu Operations Manager front end certificate, see the [Tanzu Operations Manager documentation](#).

2. (Optional) To configure multiple certificates for the Gorouter:
  1. For each additional certificate and key pair, click **Add**.
  2. Configure the fields you configured for the first certificate and key pair in the previous step. For more information about generating certificates in Tanzu Operations Manager for your wildcard system domains, see [Providing a Certificate for Your TLS Termination Point](#).

Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

## CA certificates for Gorouter

(Optional) When validating requests using mutual TLS to back ends and route services, the Gorouter trusts multiple CAs by default. To configure which CA certificates Gorouter trusts, choose one of the following options:

- For backwards compatibility with older versions of Isolation Segment:
  1. Under **Trusted CAs for client requests**, select **Trust the same CAs used for back ends and route services**.
- If you want the Gorouter to trust a particular set of CAs only:
  1. Under **Trusted CAs for client requests**, select **Only trust the following CAs**.
  2. For **Trusted client CAs**, enter the CAs you want the Gorouter to trust. The CAs you provide in this field are the only CAs that the Gorouter trusts for client requests. The Gorouter does not trust any well-known CAs that are provided with the stemcell.

## Trusted CA certificates

(Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. For **Trusted CA certificates**, enter your CA certificates appended together into a single collection of PEM-encoded entries.

## HTTP/2 protocol

(Optional) The **Use HTTP/2 protocol** check box is selected by default. When this check box is selected, the Gorouter accepts all incoming HTTP/2 requests and sends HTTP/2 requests over app routes that support HTTP/2. To deactivate HTTP/2 ingress and egress for the Gorouter, deselect the **Use HTTP/2 protocol** check box. For more information about HTTP/2 routing, see [Supporting HTTP/2](#).

Deselecting the **Use HTTP/2 protocol** check box introduces potential breaking changes for app routes.

## Enable concurrent reads/writes for HTTP/1

(Optional) To enable concurrent request reads and response writes for HTTP/1 requests in the Gorouter, select the **Enable concurrent reads/writes for HTTP/1** check box. By default, the Gorouter consumes any unread portion of the request body before beginning to write the response, preventing handlers from concurrently reading from the request and writing the response. Selecting this check box deactivates that behavior and permits handlers to continue to read from the request while concurrently writing the response.

## TLS versions

Under **TLS versions**, select the range of TLS versions to use in Gorouter communications. The Gorouter supports TLS v1.2 to TLS v1.3 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [TLS cipher suite support](#) in *Securing traffic into TAS for VMs*.

## Load balancing algorithm

(Optional) Under **Load balancing algorithm**, select either **Round-robin** or **Least-connection** as your load balancing algorithm for the Gorouter. **Round-robin** is selected by default, and VMware recommends this option for most use cases. Some use cases, such as those where apps have long-lived connections, might benefit from the least-connection algorithm. For more information, see [Router balancing algorithm](#) in *HTTP Routing*.

(Optional) Under **Load balancing algorithm availability zone preference**, select either **None** or **Locally-optimistic** as the availability zone preference for the Gorouter's load balancing algorithm. **None** is selected by default, and VMware does not recommend changing it. For more information, see [Load balancing availability zone preference](#) in *HTTP Routing*.

## Client IP logging

Under **Client IP logging**, **Log client IPs** is selected by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options:

- If your load balancer exposes its own source IP address, select **Do not log X-Forwarded-For header**.
- If your load balancer exposes the source IP address of the originating client, select **Do not log source IP or X-Forwarded-For header**.

## TLS termination point

Under **TLS termination point**, configure how TAS for VMs handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment. The table below indicates which option to choose based on your deployment configuration:

Deployment configuration	TLS option	Additional notes
<ul style="list-style-type: none"> <li>The load balancer is terminating TLS, and</li> <li>The load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header.</li> </ul>	Infrastructure load balancer	The Gorouter forwards the XFCC header when included in the request.
<ul style="list-style-type: none"> <li>The load balancer is configured to pass through the TLS handshake through TCP to instances of the Gorouter</li> </ul>	Gorouter	The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.

 If you select the **The Gorouter does not request client certificates** option in the **Gorouter behavior for client certificate validation** field, the XFCC header cannot be delivered to apps.

For a description of the behavior of each configuration option, see [Forward Client Certificate to Apps in HTTP Routing](#).

## Gorouter behavior for client certificate validation

To configure Gorouter behavior for handling client certificates, select one of the following options under **Gorouter behavior for client certificate validation**:

- The Gorouter does not request client certificates:** The Gorouter does not request client certificates, so the client does not provide them, and the Gorouter does not validate them.
- The Gorouter requests but does not require client certificates:** The Gorouter requests client certificates in TLS handshakes and validates them when they are presented, but does not require them. This option is configured by default.
- The Gorouter requires client certificates:** The Gorouter validates that the client certificate is signed by a Certificate Authority (CA) that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

Requests to the platform fail upon upgrade if your load balancer is configured with client certificates and the Gorouter is not configured with the appropriate CA. To mitigate this issue, select **The Gorouter does not request client certificates**.

## TLS cipher suites for the Gorouter

In the **TLS cipher suites for the Gorouter** field, review the TLS cipher suites for TLS handshakes between the Gorouter and front end clients such as load balancers. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`.

To modify the default configuration, use an ordered, colon-separated list of Golang-supported TLS cipher suites in the OpenSSL format. This field does not apply to TLS v1.3. For TLS v1.3, the Gorouter only uses a set of default ciphers, and this is not configurable.

Verify that the ciphers are supported by any clients or front end components that initiate TLS handshakes with the Gorouter. For a list of TLS ciphers supported by the Gorouter, see [TLS Cipher Suite Support in Securing Traffic into TAS for VMs](#).

Verify that every client participating in TLS handshakes with the Gorouter has at least one cipher suite in common with the Gorouter.

Specify cipher suites that are supported by the versions configured under **Select the range of TLS versions supported by the Gorouter**. For example, TLS v1.3 does not support configuring cipher suites. If you select **TLSv1.3 only**, you cannot configure cipher suites for the Gorouter.

AWS Classic Load Balancers do not support the TAS for VMs default cipher suites. For more information about configuring your AWS load balancers and Gorouter, see [TLS Cipher suite support by AWS load balancers](#) in *Securing traffic into TAS for VMs*.

## Reject HTTP requests

(Optional) If you want the Gorouter to reject any unencrypted traffic, select the **Reject HTTP requests** check box. When this check box is selected, the Gorouter does not listen on port `80`.

## Do not use insecure cookie

(Optional) To configure the Gorouter to only generate secure cookies, select the **Do not use insecure cookies** check box.

## Enable Zipkin tracing headers on the Gorouter

(Optional) To deactivate the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the Gorouter** check box. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [HTTP headers for zipkin tracing](#) in *HTTP routing*.

## W3C tracing headers on the Gorouter

(Optional) To activate the addition of W3C tracing headers on the Gorouter, select the **Add W3C tracing headers** check box. W3C tracing headers are disabled by default. Specify W3C tracing tenant ID name in **W3C tenant ID** field. If specified, the tracestate identifier will be "tenant-id@gorouter" where "tenant-id" is the value specified. If not specified, the tracestate identifier will be `gorouter`. For more information about using W3C trace logging headers, see [HTTP headers for W3C tracing](#) in *HTTP routing*.

## Allow the Gorouter to write access logs locally

(Optional) The **Allow the Gorouter to write access logs locally** check box is selected by default. VMware recommends deselecting this check box for high-traffic deployments, since logs might not be rotated fast enough and can fill up the disk.

## Requests to isolation segments

Under **Requests to isolation segments**, select one of the following options:

- **Accept requests for all isolation segments:** TAS for VMs Gorouters accept all traffic for apps deployed to an isolation segment created by the Isolation Segment tile. This option is selected by default.
- **Accept requests for some isolation segments:** TAS for VMs Gorouters to only accept requests for apps within specific isolation segments. If you select this option, you must also enter the names of the isolation segments for which you want TAS for VMs Gorouters to accept requests as a comma-separated list in **Isolation segment names**.
- **Reject requests for all isolation segments:** TAS for VMs Gorouters reject requests for apps within all isolation segments.

For more information, see [Installing Isolation Segment](#) and [Sharding Gorouters for isolation segments](#) in *Routing for isolation segments*.

## Accept PROXY requests

(Optional) By default, the Gorouter does not accept PROXY requests. To configure the Gorouter to accept PROXY requests, select the **Accept PROXY requests** check box. When you select this check box, client-side load balancers that stop TLS but do not support HTTP can pass along information from the originating client using the PROXY protocol. Configuring this option might impact Gorouter performance. For more information about configuring the Gorouter to accept PROXY requests, see the *About HTTP header forwarding* sections in [Securing Traffic into TAS for VMs](#).

## Route services

Under **Route services**, select either **Allow** or **Do not allow**. Route services are a class of marketplace services that perform filtering or content transformation on app requests and responses. For more information, see [Route Services](#) and [List Marketplace Services](#) in *Managing service instances with the cf CLI*.

- If you allow route services, you can also configure **Bypass security checks for route service lookup**. VMware recommends that you do not configure this field, due to potential security concerns. However, you might need to configure it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service lookup](#).

## Maximum connections per back end

(Optional) To limit the number of app connections to the back end, enter a value in **Maximum connections per back end**. Configuring this field allows you to prevent a poorly-behaving app from impacting other apps.

To allow an unlimited number of app connections to the back end, enter either `0` or no value. The default value is `500`.

To determine a value to configure in this field, review the highest number of concurrent connections that instances of the most popular apps in your deployment have received. You can determine the number of concurrent connections for an app by reviewing the `httpStartStop` event metrics emitted for each app request. If your deployment uses App Metrics, you can also find this information in your App Metrics deployment. For more information, see the [App Metrics documentation](#).

## Keep-alive connections

Under **Keep-alive connections**, select one of the following options:

- **Allow:** The Gorouter maintains TCP connections after receiving an HTTP response. This option is selected by default.
- **Do not allow:** The Gorouter closes TCP connections after receiving an HTTP response.

For more information, see [Keep-alive connections](#) in *HTTP Routing*.

## Back end request timeout and idle timeout

(Optional) For **Back end request timeout and idle timeout**, enter in seconds the amount of time that requests between the Gorouter and apps are allowed to remain idle before being closed. The default value is `900`. To accommodate larger uploads over connections with high latency, increase the value.

## Query parameter logging in Gorouter access logs

(Optional) To configure whether the Gorouter shows or hides GET request query parameters in access logs, select one of the following options under **Query parameter logging in Gorouter access logs**:

- **Log query parameters:** The Gorouter logs all query parameters without altering them.

If you select this option, GET request query parameters in Gorouter access logs might contain sensitive information.

- **Log a hash of query parameters:** The Gorouter hashes all query parameters.
- **Do not log query parameters:** The Gorouter hides all query parameters.

## Front end idle timeout

(Optional) To help prevent connections from your load balancer to the Gorouter from being closed prematurely, configure the **Front end idle timeout** field. The value you enter sets the duration, in seconds, that the Gorouter maintains an idle open connection from a load balancer that supports keep-alive connections.

To avoid the race condition where the load balancer sends a request before it discovers that the Gorouter has closed the connection, enter a value that is higher than the back end idle timeout for your load balancer.

For specific guidance and exceptions to this rule, see the following table:

IaaS	Guidance
AWS	Because AWS ELB has a default timeout of 60 seconds, VMware recommends configuring a value greater than <a href="#">60</a> .
Azure	By default, the Azure load balancer times out at 240 seconds without sending a TCP RST to clients. To force the load balancer to send the TCP RST, VMware recommends configuring a value lower than <a href="#">240</a> .
GCP	GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, VMware recommends configuring a value greater than <a href="#">600</a> . For GCP TCP load balancers, VMware recommends configuring a value less than <a href="#">600</a> to force the load balancer to send a TCP RST.
Other	Configure a value greater than that of the back end idle timeout for your load balancer.

Do not set a front end idle timeout lower than six seconds.

(Optional) For **Gorouter drain timeout**, enter in seconds the amount of time that the Gorouter continues to serve existing connections before shutting down. After the timeout is reached, all remaining connections are terminated so the Gorouter can restart. To reduce the drain time during deployments, enter a value that is lower than the values in **Back end request and idle timeout** and **Front end idle timeout**. The default value is [900](#).

## Load balancer unhealthy threshold

(Optional) Increase the value of **Load balancer unhealthy threshold** to specify the amount of time, in seconds, that the Gorouter continues to accept connections before shutting down. During this period, health checks might report the Gorouter as unhealthy, which causes load balancers to failover to other Gorouters. Configure a value that is greater than or equal to the maximum time it takes your load balancer to consider a Gorouter instance unhealthy, given repeated failed health checks.

## Load balancer healthy threshold

(Optional) Modify the value of **Load balancer healthy threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Gorouter instance started. This allows an external load balancer enough time to register the Gorouter instance as healthy.

## HTTP headers to log

(Optional) If app developers in your organization want certain HTTP request headers to appear in their app logs with information from the Gorouter, enter them as a comma-separated list under **HTTP headers to log**. For example, to support app developers that deploy Spring apps to TAS for VMs, you can enter Spring-specific HTTP request headers.

The Gorouter always logs the following HTTP request headers:

- [Referer](#)
- [User-Agent](#)

- `X-Forwarded-For`
- `X-Forwarded-Proto`
- `X-Vcap-Request-ID`

## Maximum request header size

For **Maximum request header size**, enter the maximum total size (in KB) that all headers in a request to the Gorouter might have combined, including header keys, header values, and all values in the request line. Configuring this field allows TAS for VMs to prevent denial-of-service attacks from requests with large headers.

Requests with headers that exceed this limit cause a [431](#) status code. Enter a value between [1](#) and [1024](#). VMware recommends configuring a limit of [48](#). To account for backwards compatibility, you can configure a higher limit, if required. Configuring this field does not limit the size of the request body.

If you do not configure **Loggregator port**, it defaults to [443](#). For AWS environments that are not using an Application Load Balancer, enter [4443](#).

## Container network interface plugin

For **Container network interface plugin**, select one of the following options:

- **Silk**: The default container network interface (CNI) for TAS for VMs.
- **External**: Select this option if you are deploying the [VMware NSX-T Container plug-in](#) for TAS for VMs.

If you select **External**, follow the procedure in [Deploying TAS for VMs with NSX-T Networking](#) in addition to the procedures in this topic.

The NSX-T integration only works for new installations of TAS for VMs. If your TAS for VMs tile is already deployed and configured to use Silk as its CNI, you cannot re-configure your deployment to use NSX-T.

If you selected **Silk** in the previous step, review the following fields:

1. (Optional) For **App network maximum transmission unit**, enter an MTU value in bytes. The default value is [1454](#). Some configurations might require a smaller MTU value. For example, networks that use GRE tunnels might require a smaller MTU.  
For Azure environments, VMware recommends entering [1400](#) or lower to prevent Azure from fragmenting the packets. For more information, see the [Azure documentation](#).
2. (Optional) For **Overlay subnet**, enter an IP range for the overlay network. If you do not set a custom range, Tanzu Operations Manager uses [10.255.0.0/16](#). The overlay network IP range you configure must not conflict with any other IP addresses in your network.  
Editing this property might cause container-to-container (C2C) networking downtime and security implications the next time you redeploy TAS for VMs.
3. For **Overlay subnet prefix length per Diego Cell**, enter in bits the length of the prefix for subnets allocated per Diego Cell. For example, for a [/24](#) subnet, enter [24](#). The default value is [24](#). The minimum value you can configure is [2](#). The maximum value you can configure is [30](#). Configuring a

smaller subnet allows more Diego Cells per TAS for VMs deployment, but fewer apps per Diego Cell. Conversely, configuring a larger subnet allows more apps per Diego Cell, but fewer Diego Cells per TAS for VMs deployment. The values that you configure in the **Overlay subnet** and **Overlay subnet prefix length per Diego Cell** fields determine the exact number of Diego Cells allowed per TAS for VMs deployment and apps allowed per Diego Cell.

Editing this property might cause C2C networking downtime and security implications the next time you redeploy TAS for VMs.

4. In the **VXLAN tunnel endpoint port** field, enter a UDP port number. This is the host port that receives VXLAN packets. If you do not set a custom port, Tanzu Operations Manager uses [4789](#).
  - For **Denied logging interval**, enter the per-second rate limit for packets blocked by either a container-specific networking policy or by App Security Group (ASG) rules applied across the space, org, or deployment. The default value is [1](#). For more information, see [Policies in container-to-container networking](#) and [Restricting app access to internal TAS for VMs Components](#).
  - For **UDP logging interval**, enter the per-second rate limit for UDP packets sent and received. The default value is [100](#).
  - To allow logging for app traffic, select the **Log traffic for all accepted and denied app packets** check box. Selecting this check box increases log volume. For more information, see [App traffic logging](#) in [Configuring logging in TAS for VMs](#).
5. The **Enforce Silk network policy** check box is selected by default. To deactivate Silk network policy enforcement between apps, deselect this check box. Deactivating the network policy enforcement allows all apps to send network traffic to all other apps in your TAS for VMs deployment, despite no policy specifically allowing it.  
Deactivating the **Enforce Silk network policy** check box allows all app containers to access any other app container with no restrictions.

For **DNS search domains**, enter the domains for your app containers to use as DNS search domains as a comma-separated list. Your containers append these search domains to host names to resolve them into full domain names.

## Database connection timeout

For **Database connection timeout**, enter in seconds the connection timeout for clients of the policy server and Silk databases. The default value is [120](#). You might need to increase this value if your deployment experiences timeout issues related to container-to-container networking.

## Enable TCP routing

TCP routing is deactivated by default. You can enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

1. Under **TCP routing**, select **Enable**.

If you have mutual TLS app identity verification enabled, app containers accept incoming communication only from the Gorouter. This deactivates TCP routing.

2. For **TCP routing ports**, enter one or more ports to which the load balancer forwards requests. To support multiple TCP routes, VMware recommends allocating multiple ports. Do one of these steps:
  - o To allocate a single port or range of ports, enter a single port or a range of ports.

If you configured AWS for Operations Manager manually, enter `1024-1123` which corresponds to the rules you created for `pcf-tcp-elb`.

- o To allocate a list of ports:
    1. Enter a single port in the **TCP routing ports** field.
    2. After deploying TAS for VMs, follow the procedure in [Router Groups: Modify TCP port reservations](#).
3. (Optional) For **TCP request timeout**, modify the default value of 300 seconds. This field determines when the TCP router closes idle connections from clients to apps that use TCP routes. You might want to increase this value to enable developers to push apps that require long-running idle connections with clients.
  4. Follow these additional instructions based on your IaaS:

IaaS	Instructions
GCP	Specify the name of a GCP TCP load balancer in the <b>LOAD BALANCER</b> field of the <b>TCP Router</b> job in the <b>Resource Config</b> pane. You configure this later on in TAS for VMs. For more information, see <a href="#">Configure Resources</a> .
AWS	Specify the name of a TCP ELB in the <b>LOAD BALANCER</b> field of the <b>TCP Router</b> job in the <b>Resource Config</b> pane. You configure this later on in TAS for VMs. For more information, see <a href="#">Configure Resources</a> .
Azure	Specify the name of a Azure load balancer in the <b>LOAD BALANCER</b> field of the <b>TCP Router</b> job in the <b>Resource Config</b> pane. You configure this later on in TAS for VMs. For more information, see <a href="#">Configure Resources</a> .
OpenStack and vSphere	<ol style="list-style-type: none"> <li>1. Return to the top of the <b>Networking</b> pane.</li> <li>2. In the <b>TCP router IPs</b> field, ensure that you have entered IP addresses that are within your subnet CIDR block. These are the same IP addresses you configured your load balancer with in the <a href="#">Pre-Deployment Steps</a> in <i>Enabling TCP Routing</i>, unless you configured DNS to resolve the TCP domain name directly to an IP you have chosen for the TCP router.</li> </ol>

#### Additional settings:

- (Optional) For additional security, under **HTTP response headers to remove**, enter headers that you want the Gorouter to remove from app responses in the **Header name** field.
- (Optional) Under **Sticky session cookies**, enter one or more sticky session cookie names in the **Cookie name** field. The default cookie name is `JSESSIONID`. Some apps require a different cookie name. For example, Spring WebFlux requires `SESSION` for the cookie name. Gorouter uses these cookies to support session affinity, or *sticky sessions*. For more information, see [Session Affinity](#) in *HTTP Routing*.
- For **Internal route staleness threshold**, enter the amount of time, in seconds, that the Service Discovery Controller waits to receive messages about routes before pruning them from the routing table.

Remember to click **Save**.

## App containers

In the **App Containers** pane, you configure microservice frameworks, private Docker registries, and other services that support your apps at the container level.

To configure the **App Containers** pane:

1. Select **App Containers**.
2. The **Allow custom buildpacks** check box governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. This check box is selected by default, letting developers use custom buildpacks when deploying apps. To disallow the use of custom buildpacks, deselect the **Allow custom buildpacks** check box. For more information about custom buildpacks, see [Using Classic Buildpacks in Cloud Foundry](#).
3. The **Allow SSH access to app containers** check box controls SSH access to app instances. To allow SSH access across your deployment, select the **Allow SSH access to app containers** check box. To prevent all SSH access, deselect the **Allow SSH access to app containers** check box. For more information about SSH access permissions at the space and app level, see [App SSH overview](#).

To allow SSH traffic, ensure that port `2222` is open on your load balancer.

You can give SSH access to an app only if an admin assigns you a Space Developer role in the space where the app runs. For more information, see [Manage App Space Roles](#) in *Managing User Roles with Apps Manager*.

4. To allow SSH access for new apps by default in spaces that allow SSH, select the **Allow SSH access when an app is created** check box. If you deselect this check box, developers can still allow SSH access after pushing their apps by running `cf enable-ssh APP-NAME`, where `APP-NAME` is the name of the app.
5. (Optional) To give apps that generally stay within their CPU entitlements priority access to extra CPU during CPU bursts, select the **Allow CPU burst optimization** check box. This check box is selected by default. When this check box is selected, apps that generally stay within their CPU entitlements have higher-priority access to extra CPU than apps that generally exceed their CPU entitlements. When this check box is deselected, all apps have equal access to extra CPU during CPU bursts. Whether you select or deselect this check box, all apps are always guaranteed the amount of CPU that is within their CPU entitlements.
6. Under **Gorouter app identity verification**, choose how the Gorouter verifies app identity to allow encryption and prevent misrouting:

This feature does not work if **The Gorouter does not request client certificates** is selected under **Gorouter behavior for client certificate validation** in the **Networking** pane.

- **The Gorouter uses TLS to verify app identity:** Allows the Gorouter to verify app identity using TLS. This option is selected by default.
- **The Gorouter and apps use mutual TLS to verify each other's identity:** Allows your apps and the Gorouter to verify each other's identity using mutual TLS (mTLS). This option deselects TCP routing because app containers accept incoming communication only from the Gorouter.

For more information, see [Preventing misrouting in HTTP Routing](#).

7. To configure TAS for VMs to run app instances in Docker containers, enter a comma-separated list of their IP address ranges in the **Docker registry allow list** field. For more information, see [Using Docker Registries](#).
8. Under **Diego Cell disk cleanup scheduling**, select one of the following options:
  - **Never clean up disk space:** Diego Cells never schedule disk cleanups. VMware does not recommend selecting this option for production environments.
  - **Routinely clean up disk space:** Diego Cells schedule a disk cleanup whenever a container is created. Running the disk cleanup process this frequently can negatively impact Diego Cell performance.
  - **Clean up disk space once usage fills disk:** Diego Cells schedule a disk cleanup only when disk use encroaches on the space reserved for other jobs. If you select this option, enter in MB the amount of space that you want the garbage collection algorithm to keep free for other jobs in the **Reserved disk space for other jobs** field. For more information about the configuration options and how to configure a reserved amount, see [Configuring Diego Cell Disk Cleanup Scheduling](#).
9. The **Allow containerd delegation** check box governs whether Garden delegates container create and destroy operations to the containerd tool. This check box is selected by default. To disallow Garden delegating container create and destroy operations to containerd, deselect the **Allow containerd delegation** check box. For more information about the containerd tool, see the [containerd](#) website.
10. For **Maximum in-flight container starts**, enter the maximum number of started instances you want to allow across all Diego Cells in your deployment. Entering `0` sets no limit. The default value is `200`. For more information, see [Set a maximum number of started containers](#) in *Configuring TAS for VMs for Upgrades*.
11. Under **NFSv3 volume services**, select **Allow** or **Do not allow**. Deploying NFS volume services allows app developers to bind existing NFS volumes to their apps for shared file access. For more information, see [Enabling Volume Services](#).

In a new installation of TAS for VMs, the **NFSv3 volume services** check box is selected by default. When you upgrade from an earlier version of TAS for VMs, the **NFSv3 volume services** check box is automatically configured the same way it was configured in the earlier version.

12. (Optional) To configure LDAP for NFSv3 volume services:

- For **LDAP service account user**, enter the user name of the service account in LDAP that manages volume services.
- For **LDAP service account password**, enter the password for the service account.
- For **LDAP server host**, enter the hostname or IP address of the LDAP server.
- For **LDAP server port**, enter the LDAP server port number. If you do not specify a port number, Tanzu Operations Manager uses [389](#).
- For **LDAP user search base**, enter the location in the LDAP directory tree from which any LDAP user search begins. The typical LDAP search base matches your domain name. For example, a domain named `cloud.example.com` typically uses `ou=Users,dc=example,dc=com` as its LDAP user search base.
- (Optional) If your LDAP server supports TLS and you want to allow TLS connections from the NFS driver to your LDAP server, enter the root certificate from your CA certificate or your self-signed certificate in **LDAP server CA certificate**.

UAA can parse only one certificate entered into this text box. If you enter multiple certificates, UAA uses only the first one you entered and ignores the rest. You need one root certificate or self-signed certificate.

13. (Optional) To deploy SMB volume services, select the **Allow SMB volume services** check box. Deploying SMB volume services allows developers to bind existing SMB shares to their apps. For more information, see [Enabling Volume Services](#).

If you deploy SMB volume services, you must set the **SMB Broker Errand** to **On** in the **Errands** pane.

14. (Optional) To force all SMB shares to mount with the `noserverino` mount option, select the **Force noserverino mount option for SMB mounts** check box.
15. (Optional) To modify the amount of time that health checks wait to receive a healthy response from an app before the app is declared unhealthy, enter the number of seconds you want the timeout period to last in **Default health check timeout**. If the health check does not receive a healthy response from a newly-started app within the configured timeout period, then the app is declared unhealthy. The default value is [60](#). The maximum value you can configure is [600](#).  
If you decrease the default health check timeout below its current value, existing apps with startup times greater than the new value might fail to start up.
16. (Optional) To limit the number of log lines an app instance can generate per second, select **Enable** under **App log rate limit (deprecated)** and enter an integer for **Maximum app log lines per second**. At minimum, VMware recommends using the default limit of [100](#). This feature is deactivated by default.

This method of limiting log output from applications is deprecated. VMware recommends using the log rate limiting quota feature which provides more granular control over application log output.

17. Click **Save**.

## App Developer Controls

In the **App Developer Controls** pane, you configure restrictions and default settings for your apps.

To configure the **App Developer Controls** pane:

1. Select **App Developer Controls**.
2. Enter the **Maximum file upload size** in MB. This is the maximum size of an app upload, including the buildpack.
3. Enter the **Maximum package size** in MB. This is the maximum total size of an app's files.
4. Enter the **Default app memory** in MB. This is the default amount of memory allocated to a newly-pushed app if no value is specified when pushing the app.
5. Enter the **Default app memory quota per org** in MB. This is the default memory limit for all apps in an org. The specified limit only applies to the first installation of TAS for VMs. After the initial installation, operators can use the cf CLI to change the default value.
6. For **Maximum disk quota per app** in MB, enter in MB the maximum amount of disk allowed per app.

If you allow developers to push large apps, TAS for VMs might have trouble placing them on Diego Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger apps might not successfully redeploy if there is insufficient disk capacity. Monitor your deployment to ensure that your Diego Cells have sufficient disk to run your apps.

7. Enter the **Default disk quota per app** in MB. This is the amount of disk allocated by default to a newly-pushed app if no value is specified when pushing the app.
8. Enter the **Default log rate limit per app** in bytes per second. This is the number of logs that a newly-pushed app is allowed to send to Loggregator if no value is specified when pushing the app.

To deactivate this feature and allow app instances to send an unlimited number of logs to Loggregator, enter `-1`. App log rate limiting is deactivated by default. VMware recommends activating this feature to prevent app instances from overloading the Loggregator Agent with logs, so the Loggregator Agent does not drop logs for other app instances on the same Diego Cell.

9. Enter the **Default service instance quota per org**. The specified limit only applies to the first installation of TAS for VMs. After the initial installation, operators can use the cf CLI to change the default value.
10. Enter the **Staging timeout** in seconds. When you stage an app droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
11. For **Internal domains**, enter one or more domains that apps use for internal DNS service discovery. If the `-d` flag for domain is not available, you can specify a domain using the `routes` property in the manifest so other TAS for VMs apps can reach the pushed app at `APP-NAME.INTERNAL-DOMAIN`. This value defaults to `apps.internal`.
12. Activate the **Allow space developers to manage network policies** check box to permit developers to manage their own network policies for their apps.

13. Activate the **Log revision number in app logs** check box include app revision id as well in apps' log sources. (e.g. logs will have prefixes like APP/REV/1/PROC/WEB/0 instead of APP/PROC/WEB/0.). Once activated, apps will need to be restarted to take effect. Only applies to apps with the revision feature flag activated.

14. Click **Save**.

Setting appropriate ASGs is critical for a secure deployment.

1. Select **App Security Groups**.
2. Acknowledge **You are responsible for setting the appropriate ASGs after TAS for VMs finishes deploying**.
3. Click **Save**.

For more information about ASGs, see [App Security Groups](#).

For more information about setting ASGs, see [Restricting App Access to Internal TAS for VMs Components](#).

## Authentication and enterprise SSO

In the **Authentication and Enterprise SSO** pane, you configure your user store access.

To configure the **Authentication and Enterprise SSO** pane:

1. Select **Authentication and Enterprise SSO**.
2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server. To configure the user database that your deployment uses to authenticate users, select one of the following options under **User authentication mechanism**:
  - To use the internal UAA instance, select **Internal user store** and follow the procedure in [Configuring UAA password policy](#) to configure your password policy.
  - To connect to an external identity provider through SAML, select **SAML identity provider** and follow the procedure in [Configure TAS for VMs to use a SAML identity provider](#) in [Configuring Authentication and Enterprise SSO for TAS for VMs](#).
  - To connect to an external LDAP server, select **LDAP server** and follow the procedure in [Configure LDAP as an identity provider for TAS for VMs](#) in [Configuring Authentication and Enterprise SSO for TAS for VMs](#).
  - To use an external OIDC identity provider, select **OIDC identity provider** and follow the procedure in [Configure TAS for VMs to Use an OIDC identity provider](#).
3. Click **Save**.

## UAA

In the **UAA** pane, you configure the User Account and Authentication (UAA) server.

To configure the **UAA** pane:

1. Click **UAA**.

2. Under **UAA database location**, select one of these options:

- **Tanzu Application Service database:** Use the same database server that other TAS for VMs components use. This system database is configured in the **Databases** pane, and it can be either internal or external.
- **External database:** Use a separate, dedicated database server for UAA. For GCP installations, VMware recommends using an external database on Google Cloud SQL.

Protect whichever database you use in your deployment with a password.

3. (Optional) If you selected **External database**, complete these fields as follows.

- For **Hostname**, enter the hostname of the database server.
- For **TCP port**, enter the port of the database server.
  - **AWS Terraform:** Enter the value of `rds_port` in the Terraform output.
  - **GCP and GCP Terraform:** Enter `3306`.
- For **Username**, specify a unique user name that can access this database on the database server.
  - **AWS Terraform:** Enter the value of `rds_username` from your Terraform output.
  - **GCP Terraform:** Enter the value of `tas_sql_username` from your Terraform output.
- For **Password**, specify a password for the provided user name.
  - **AWS Terraform:** Enter the value of `rds_password` from your Terraform output.
  - **GCP Terraform:** Enter the value of `tas_sql_password` from your Terraform output.
- For **Username**, specify a unique user name that can access this specific database on the database server.
- For **Password**, specify a password for the provided username.
- For **CA certificate**, enter a certificate to use for encrypting traffic to and from the database.

The **CA certificate** text box only works if your external database host name matches a name specified in the certificate. This is not true with GCP CloudSQL.

4. (Optional) Under **JWT issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.
5. Under **SAML service provider credentials**, enter a certificate and private key to be used by UAA as a SAML service provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a certificate. The domain `*.login.SYSTEM-DOMAIN` must be associated with the certificate, where `SYSTEM-DOMAIN` is the **System domain** you configured in the **Domains** pane.

The Operations Manager Single Sign-On Service and Operations Manager Spring Cloud Services tiles require the `*.login.SYSTEM-DOMAIN`.

6. Under **SAML service provider credentials**, enter a certificate and private key to be used by UAA as a SAML service provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a certificate. The domain `*.login.SYSTEM-DOMAIN` must be associated with the certificate, where `SYSTEM-DOMAIN` is the **System domain** you configured in the **Domains** pane.

The Operations Manager Single Sign-On Service and Operations Manager Spring Cloud Services tiles require the `*.login.SYSTEM-DOMAIN`.

7. If the private key specified under **SAML service provider credentials** is password-protected, enter the password under **Private key password**.
8. (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID override** text box. By default, the SAML Entity ID is `http://login.SYSTEM-DOMAIN`, where `SYSTEM-DOMAIN` is the **System domain** you configured in the **Domains** pane.
9. For **Signature algorithm**, choose an algorithm from the drop-down menu to use for signed requests and assertions. The default value is **SHA256**.
10. (Optional) In the **Apps Manager access token lifetime**, **Cloud Foundry CLI access token lifetime**, and **Cloud Foundry CLI refresh token lifetime** text boxes, change the lifetimes of tokens granted for Apps Manager and cf CLI login access and refresh. Most deployments use the defaults.
11. (Optional) In the **Global login session maximum timeout** and **Global login session idle timeout** text boxes, change the maximum number of seconds before a global login times out. These text boxes apply to:
  - **Default zone sessions:** Sessions in Apps Manager, Operations Manager Metrics, and other web UIs that use the UAA default zones.
  - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Operations Manager Single Sign-On service plan.
12. (Optional) Customize the text prompts used for the user name and password from the cf CLI and Apps Manager login pop-up by entering values for **Username label** and **Password label**.
13. (Optional) The **Proxy IPs regular expression** field text box contains a pipe-separated set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
14. (Optional) Deselect the **Client basic auth compatibility mode** check box to require URL encoding for UAA client basic authentication credentials. By default, the check box is selected and URL encoding is not required. This represents the default behavior of UAA before UAA v74.0.0. URL encoding is defined by RFC6749. For more information, see [RFC6749](#). To require URL encoding for certain UAA clients without deactivating compatibility mode, use the `X-CF-ENCODED-CREDENTIALS=true` HTTP header.

If you deselect the **Client basic auth compatibility mode** check box, URL encoding is required for all UAA client apps in your deployment. To avoid breaking changes, ensure that all client apps support URL encoding before you deselect the check box.

15. (Optional) If you are using [Single Sign-On for VMware Tanzu Application Service](#) and you want to honor the CORS policy for custom identity zones, deselect the **Enforce system zone CORS policy across all identity zones** check box. This check box is selected by default. If you use Single Sign-On, UAA creates custom identity zones. If you leave this check box selected, UAA ignores the CORS policy for custom identity zones and applies the system default identity zone CORS policy to all zones.

If you deselect the **Enforce system zone CORS policy across all identity zones** check box, apps that are integrated with Single Sign-On might experience downtime because the default CORS policy of the custom identity zones is more restrictive. To prevent downtime, you must explicitly set the CORS policy of the custom identity zones according to the needs of your apps. For more information, see the [Managing Service Plan Configurations](#) in the Single Sign-On documentation.

16. (Optional) To override the default UAA internal user password policies, see [Configuring UAA password policy](#).
17. Click **Save**.

## CredHub

In the **CredHub** pane, you configure the CredHub server.

To configure the **CredHub** pane:

1. Select **CredHub**.
2. Under **CredHub database location**, select the location of your CredHub database. TAS for VMs includes this CredHub database for services to store their service instance credentials.
  - **TAS for VMs database**: If you select this option, CredHub uses the same database as other TAS for VMs components, whether the database is internal or external. You configure this database in the **Databases** pane.
  - **External database**: If you select this option, configure these fields:
    - **Hostname**: Enter the IP address of your database server.
    - **TCP port**: Enter the port of your database server, such as [3306](#).
    - **Username**: Enter a unique username to use to access your CredHub database on the database server.
    - **Password**: Enter the password for the provided username.
    - **CA certificate**: This certificate is used when encrypting traffic to and from the CredHub database. For certificate rotation, you may enter multiple CA certificates

in this field.

- **Skip hostname verification:** Select if you don't want CredHub to verify the identity of your database server during TLS connections. You cannot deactivate hostname verification for TLS connections to Postgres databases. You must select this option if you are configuring an external database on GCP or Azure.

If you deploy TAS for VMs on AWS using Terraform, you can locate these values in your Terraform output:

- **Hostname:** `rds_address`
- **TCP port:** `rds_port`
- **Username:** `rds_username`
- **Password:** `rds_password`

3. (Optional) Under **KMS providers**, specify one or more Key Management Service (KMS) providers:
  - **Name:** Enter the name of the KMS provider.
  - **Endpoint:** Enter the Unix socket address for the KMS plug-in.
  - **Primary:** Activate the **Primary** check box to indicate the primary KMS provider for your environment. You must mark one provider as primary. Do not mark more than one provider as primary.
4. Under **Internal encryption provider keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.
  - If you plan to use internal encryption, configure these fields:
    - **Name:** Enter any key name.
    - **Key:** Enter a randomly generated value that is at least 20 characters long. This key is used for encrypting all data.
    - **Primary:** This check box marks the key you specified as the primary encryption key. You must mark one key as primary. Do not mark more than one key as primary.
  - If you plan to use a hardware security module (HSM) as your encryption provider, configure these fields:
    - **Name:** Enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM provider partition** that you configure.
    - **Key:** Enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
    - **Primary:** This check box is used for marking the key you specified as the primary encryption key. You must mark one key as primary. Do not mark more than one key as primary.

For information about using additional keys for key rotation, see [Rotating Runtime CredHub Encryption Keys](#).

5. (Optional) To configure CredHub to use an HSM, configure these fields:

- **HSM provider partition:** Enter the name of the HSM provider partition.
  - **HSM provider partition password:** Enter a password to use to access the HSM provider partition.
  - **HSM provider client certificate:** Enter the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in *Preparing CredHub HSMs for Configuration*.
  - Under **HSM provider encryption keys**, specify one or more keys to use for encrypting and decrypting the values stored in the HSM provider. For each key, configure these fields:
    - **Name:** Enter the name of the encryption key.
    - **Primary:** This check box is used for marking the key you specified as the primary encryption key. You must mark one key as primary. Do not mark more than one key as primary.
  - In the **HSM provider servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, configure these fields:
    - **Host address:** Enter the hostname or IP address of the HSM server.
    - **Port:** Enter the port of the HSM server. If you do not know your port address, enter [1792](#).
    - **Partition serial number:** Enter the serial number of the HSM partition.
    - **HSM certificate:** Enter the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.
6. If your deployment uses any Operations Manager services that support storing service instance credentials in CredHub and you want to activate this feature, activate the **Secure service instance credentials** check box. For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).
  7. Click **Save**.
  8. Go to the **Resource Config** pane.
  9. Under the **Job** column of the **CredHub** row, ensure that the number of instances is set to [2](#). This is the minimum instance count required for high availability.
  10. To configure CredHub so it detects a proxy, complete the following fields:
    - **Proxy servers:** Enter a comma-separated list of router IP addresses for the first group of HTTP/TCP backends.
    - **HTTP proxy URL:** Enter the [http\\_proxy](#) for all HTTP requests across VMs.
    - **HTTPS proxy URL:** Enter the [https\\_proxy](#) for all HTTPS requests across VMs
    - **Excluded hosts:** Enter a comma-separated list of domains, IP addresses, or DNS suffixes to exclude from proxying.
  11. Click **Save**.

## Databases

In the **Databases** pane, you can configure TAS for VMs to use an internal MySQL database provided with Operations Manager, or you can configure an external database provider for the databases required by TAS for VMs.

If you are performing an upgrade, do not modify your existing internal database configuration, or you might lose data. You must migrate your existing data first before changing the configuration. For additional upgrade information, see [Upgrading Operations Manager](#). ## Internal system database configuration

For GCP installations, VMware recommends selecting **External** and using Google Cloud SQL. Only use internal MySQL for non-production or test installations on GCP.

To configure internal databases for your deployment:

1. Under **System databases location**, select **Internal MySQL clusters**.
2. Click **Save**.

To configure high availability for your internal MySQL databases, see [Configure Internal MySQL](#).

## External system database configuration

To configure external databases for your deployment:

1. Ensure that you have a database instance with the following databases created:
  - account
  - app\_usage\_service
  - autoscale
  - ccdb
  - credhub
  - diego
  - locket
  - networkpolicyserver
  - nfsvolume
  - notifications
  - routing
  - silk
  - uaa

The steps to create external databases vary depending on your database type. For an example procedure, see [Creating databases for TAS for VMs](#).

2. In the TAS for VMs tile, select **Databases**.
3. Under **System databases location**, select **External database server**.

If you configure external databases, you cannot configure an internal database in the **UAA** pane.

4. For **Hostname**, enter the hostname of your external database server.
5. The **Require hostname validation** check box is selected by default. When this check box is selected and you configure your external databases to communicate over TLS, TAS for VMs verifies the hostname of the external database during communication between TAS for VMs and the external database.

If your deployment uses a GCP or Azure external database for TAS for VMs that is configured to use TLS, you must deselect the **Require hostname validation** check box. For more information, see [Deactivate Hostname Validation for External Databases on GCP and Azure](#) in *Upgrade Preparation Checklist for Tanzu Operations Manager v2.10*.

The **Require hostname validation** check box does not affect communication between TAS for VMs components and external CredHub databases. To configure hostname validation for the CredHub external database, see [Configure CredHub](#).

6. For **TCP port**, enter the port of your external database server. If you are using GCP CloudSQL as your external database server, enter **3306**.
7. Each component that requires a relational database has two corresponding fields: one for the database user name, and one for the database password. For each set of fields, specify a unique user name that can access this specific database on the database server and a password for the provided user name.

- Ensure that the `networkpolicyserver` database user has the **ALL PRIVILEGES** permission.
- If CredHub uses the same database as other TAS for VMs components, you must configure the **CredHub database username** and **CredHub database password** fields.
- If UAA uses the same database as other TAS for VMs components, you must configure the **UAA database username** and **UAA database password** fields.
- If you are configuring an external database on GCP or Azure and want to use this database for CredHub, do not configure the **CredHub database username** and **CredHub database password** fields. Instead, you must enter these credentials in the **CredHub** pane of the TAS for VMs tile.

8. (Optional) To configure your external databases to communicate over TLS, enter a CA certificate in **CA certificate**.

TAS for VMs does not support TLS communication for databases that do not include a matching hostname in their server certificate, such as Azure and GCP, unless you deselect the **Require hostname validation** check box and select the **Skip hostname verification** check box in the **CredHub** pane of the TAS for VMs tile. For more information, see the [GCP documentation](#). To configure the **Skip hostname verification** check box, see [Configure CredHub](#).

- Click **Save**.

## File storage

### Important

Some blobstores, for example, Oracle Cloud Infrastructure Object Storage, do not support S3 Signature v4 Streaming. To use blobstores without S3 Signature v4 Streaming support with VMware Tanzu Application Service for VMs, deselect the Signature v4 streaming check box.

For more information, see [AWS-S3 Signature v4 Streaming](#).

In **File Storage**, you determine where you want to place the file storage for your Cloud Controller.

To configure the **File Storage** pane:

- Select **File Storage**.
- For **Maximum valid packages per app**, enter the maximum number of recent valid packages that your app can store, not including the package for the current droplet. VMware recommends using the default value of [2](#). However, you can lower the value if you have strict storage requirements and want to use less disk space.
- For **Maximum staged droplets per app**, enter the maximum number of recent valid droplets that your app can store, not including the package for the current droplet. VMware recommends using the default value of [2](#). However, you can lower the value if you have strict storage requirements and want to use less disk space.
- Under **File storage backup level**, select what you want to back up from your blobstores:
  - Complete file storage backup:** Includes the entire blobstore. This includes droplets, packages, and buildpacks.
  - Exclude droplets from file storage backup:** Excludes droplets from your backup. If you select this option, you must re-stage all apps during a restore.
  - Exclude droplets and packages from file storage backup:** Excludes droplets and packages from your backup. If you select this option, you must re-push all apps during a restore.

For more information about the advantages and disadvantages of excluding droplets and packages, see [File storage backup level](#).

- To configure **Cloud Controller filesystem**, see [Configuring file storage for TAS for VMs](#).

# Cloud Controller

In the **Cloud Controller** pane, you configure the Cloud Controller.

To configure the **Cloud Controller** pane:

1. Click **Cloud Controller**.
2. Enter your **Cloud Controller database encryption key** if all of the following are true:
  - You deployed TAS for VMs previously.
  - You then stopped TAS for VMs or it ended.
  - You are redeploying TAS for VMs with a backup of your Cloud Controller database.

For more information, see [Backing up and restoring Operations Manager](#).
3. Cloud Foundry API rate limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. Under **Cloud Foundry API rate limiting**, select one of the following options:
  - To configure Cloud Foundry API rate limiting:
    1. For **General limit**, enter the number of requests a user or client is to be allowed to make over an hour-long interval for all endpoints that do not have a custom limit. The default value is `2000`.
    2. For **Unauthenticated limit**, enter the number of requests an unauthenticated client is to be allowed to make over an hour-long interval. The default value is `100`.
  - To disallow Cloud Foundry API rate limiting, select **Do not use**.
4. (Optional) For **Database connection validation timeout**, enter in seconds the database connection validation timeout period you want to configure. The default value is `3600`. To configure Cloud Controller to make an additional query to the database whenever connections are checked out from the pool, enter `-1`. Configuring `-1` in this field has performance implications.
5. (Optional) For **Database read timeout**, enter in seconds the database read timeout period you want to configure. The default value is `3600`.
6. (Optional) For **Cloud Controller monit health check timeout**, enter in seconds the amount of time to wait before an HTTP request from the Cloud Controller monit health check is closed. The default value is `6`.
7. (Optional) For **Age of audit events pruned from Cloud Controller database**, enter in days the age at which audit events are to be pruned from the Cloud Controller database. The default value is `31`.
8. (Optional) For **Age of completed tasks pruned from Cloud Controller database**, enter in days the age at which completed tasks are to be pruned from the Cloud Controller database. The default value is `31`.
9. (Optional) Rotate the Cloud Controller database (CCDB) encryption key using the **Encryption key ledger** field. For more information, see [Rotating the Cloud Controller database encryption key](#).

10. For **Available Stacks**, configure the set of stacks you want to make available to app developers on the platform:
  1. Select the stacks to expose to developers. `cflinuxfs4` is the latest stack, based on Ubuntu Jammy Jellyfish (22.04), and is recommended. `cflinuxfs3`, an older stack based on Ubuntu Bionic Beaver (18.04), remains supported as well. Lastly, `tanzu-jammy` refers to the Tanzu [Jammy Full stack](#). This stack uses the same operating system as `cflinuxfs4`, but is based on the Paketo stacks. Operators have the following four configuration options:
    - `cflinuxfs4` only
    - `cflinuxfs3` and `cflinuxfs4`
    - `cflinuxfs4` and `tanzu-jammy`
    - `cflinuxfs3`, `cflinuxfs4`, and `tanzu-jammy`
  2. Select a **Default stack**. This stack is used whenever an app is pushed with no stack specified. The available options are `cflinuxfs3` and `cflinuxfs4`. `tanzu-jammy` is not supported as a default stack. If you select a stack list that does not include `cflinuxfs3`, then `cflinuxfs4` is used as the default stack.
11. (Optional) **Number of local workers per Cloud Controller VM**. Defaults to 2. See [Scaling Local Workers](#) for more information.
12. (Optional) **Enable Prometheus metrics for Cloud Controller**. Defaults to disabled. For more information, see [Cloud Controller metrics](#).
13. (Optional) **Enable StatsD metrics for Cloud Controller**. Defaults to enabled. For more information, see [Cloud Controller metrics](#).
14. (Optional) **Enable Cloud Controller web server to utilize multiple CPU cores and automatically set the number of Puma workers**. This allows the Cloud controller API VMs to utilize multiple CPU cores and lets Puma automatically set the number of workers based on the number of available cores. This uses the Ruby Puma web server instead of Thin. This feature uses a different format for primary metrics (Prometheus). For more information on these properties see [Scaling Puma Web Server](#) and more information on migration see [Cloud Controller Multi-Process Mode \(Puma\)](#).
  1. Select the number of Puma Workers. This is the number of child process to run as part of Puma clustered mode. This should not exceed the number of CPU cores available to the Cloud Controller API VM. The number of CPU cores can be found on the **Resource Config** page in the Ops Manager UI.
  2. Maximum number of threads per Puma Workers. For Cloud Controller running Puma to be able to handle as many concurrent requests as an API server running Thin, it's recommended that Number of Workers x Number of Threads is greater or equal to 20. Default threads is `10`.
  3. Maximum database connections per Puma Worker. The total number of connections is equal to Number of Workers x Maximum database connections per Worker. Be aware that incorrectly setting this may lead to too many connections for your Database. See [Scaling Puma Web Server](#) for more information.

To reduce the number of Cloud Controller API VMs, use Multi-Process Mode as described in [Cloud Controller Multi-Process Mode](#) or increase the number of local workers per Cloud Controller VM as described in [cloud\\_controller\\_worker\\_local](#).

15. Click **Save**.

## Smoke tests

In the **Smoke Tests** pane, you configure where smoke tests are run. In this location, the Smoke Tests errand pushes an app to a Operations Manager org to run basic function tests against the TAS for VMs tile after an installation or update. In the **Errands** pane, you can choose whether or not to run the Smoke Tests errand.

To configure the **Smoke Tests** pane:

1. Select **Smoke Tests**.
2. In the **Smoke tests location**, select one of the following options to configure where TAS for VMs pushes an app to run smoke tests:
  - If you have a shared apps domain, select **A temporary space within the system org**. This creates a temporary space within the `system` org for running smoke tests and deletes the space afterwards.
  - If you do not have a shared apps domain:
    1. Select **A specified domain, org, and space**.
    2. For **Domain**, enter the domain that TAS for VMs uses when pushing an app to run smoke tests.
    3. For **Org**, enter the org that TAS for VMs uses when pushing an app to run smoke tests.
    4. For **Space**, enter the space that TAS for VMs uses when pushing an app to run smoke tests.
3. Click **Save**.

## Errands

Errands are scripts that Tanzu Operations Manager runs automatically when it installs or uninstalls a product, such as a new version of TAS for VMs. There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Tanzu Operations Manager always runs all errands.

In the **Errands** pane, you can change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Tanzu Operations Manager manages errands, see [Managing Errands in Tanzu Operations Manager](#).

Several errands, such as **App Autoscaler** and **Notifications**, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the

corresponding errand on a subsequent installation does not stop the app.

- The **Smoke Test Errand** verifies that your deployment can do the following:
  - Push, scale, and delete apps
  - Create and delete orgs and spaces
- The **Usage Service Errand** deploys the Usage Service app on which Apps Manager depends.
- The **Offline Docs Errand** deploys an offline documentation app that can be used in air-gapped environments.
